

180. (Unchanged) The method of claim 179, further comprising a step of generating said passed only a portion of said second completed full-screen video graphic image in accordance with said at least one processor instruction.

181. (Unchanged) The method of claim 179, further comprising the steps of receiving audio from said remote transmitter station, and outputting said audio at a speaker during said video graphic presentation.

182. (Unchanged) The method of claim 181 wherein said audio states a significance of information displayed in said video graphic presentation.

II. REMARKS

A. Introduction

Applicants have carefully reviewed the Office Action originally issued on October 19, 1999 and reissued on January 7, 2000, (Office Action) and have made the foregoing amendments in response thereto.

1. Claim Accounting

Claims 56, 58, 60, 65-67, 69, 72, 73, 75-79, 81, 86, 88, 93, 96, 102, 104-107, 109, 112, 113, 116, 117, 122-124, 126-135, 139-143, 147, 149-153, 155, 161, 162, 164-166, 171 and 175 are amended. Claims 56-182 are pending in the application. On page 80 of the Office Action the Examiner states, "there is, factually, no pending claim 182." Contrary to the Examiner's assertion, Applicants added new claims 93-182 in the Supplemental Amendment filed March 4, 1999. Claim 182 appears on page 50 of the Supplemental Amendment. Applicants respectfully submit that the instant application does in fact include pending claim 182. Applicants present no new matter in the

foregoing amendments. Applicants respectfully request approval and entry of this amendment.

2. Summary of Jan. 7, 2000 Office Action rejections

The following summarizes the objections and rejections of the January 7, 2000 Office Action with respect to its corresponding paragraph numbers:

4. The amendment of March 4, 1999 is objected to under 35 U.S.C. § 132 alleging the introduction of new matter.
6. The oath or declaration is defective under 37 C.F.R. § 1.67(a).
8. Claims 56-181 are rejected under 35 U.S.C. § 112, first paragraph, as containing subject matter which was not described in the specification in such a way as to reasonably convey to one skilled in the relevant art that the inventor, at the time the application was filed, had possession of the claimed invention.
9. Claims 61 & 63 are rejected under 35 U.S.C. § 112, first paragraph, as containing subject matter which was not described in the specification in such a way as to reasonably convey to one skilled in the relevant art to which it pertains, or with which it is most nearly connected, to make and/or use the invention.
10. Claims 56, 58-59, 62-65, 69, 75, 77, 79, 81, 101, 109-110, 112, 115, 122, 126, 129, 141, 146, 151, 152 (and all claims depending therefrom) are rejected under 35 U.S.C. § 112, first paragraph, as containing subject matter which was not described in the specification in such a way as to reasonably convey to one skilled in the relevant art to which it pertains, or with which it is most nearly connected, to make and/or use the invention.
11. Claims 56-181 are rejected under 35 U.S.C. § 112, first paragraph, because the best mode contemplated by the inventor has not been disclosed.
13. Claims 56-181 are rejected under 35 U.S.C. § 112, second paragraph, as failing to set forth the subject matter which Applicants regard as their invention.

14. Claims 56-181 are rejected under 35 U.S.C. § 112, second paragraph as being indefinite for failing to particularly point out and distinctly claim the subject matter which Applicants regard as the invention.

19. Claims 56-181 are rejected under 35 U.S.C. § 112, first paragraph, as containing subject matter which was not described in the specification in such a way as to reasonably convey to one skilled in the relevant art to which it pertains, or with which it is most nearly connected, to make and/or use the invention.

20. Claims 56-181 are rejected under 35 U.S.C. § 102(b) as being clearly anticipated by Applicants' U.S. Pat. Nos. 4,694,490 and 4,704,725.

21. Claims 56-181 are rejected under 35 U.S.C. § 102(a, b & e) as being clearly anticipated by any of Campbell et al. (102(a) for PCT & 102(e&b) for abandoned parent application no. 135,987).

22. Claims 56-181 are rejected under 35 U.S.C. § 102(e) as being clearly anticipated by Jeffers et al. U.S. Pat. No. 4,739,510.

23. Claims 56-181 are rejected under 35 U.S.C. § 103(a) as being unpatentable over Campbell et al. or Jeffers et al. in view of Applicants' U.S. Pat. Nos. 4,694,490 and 4,704,725.

24. Claims 56-181 are rejected under 35 U.S.C. § 103(a) as being unpatentable over Applicants' WO 89/02682.

25. Claims 56-181 are rejected under 35 U.S.C. § 103(a) as being unpatentable over all of: Campbell et al. alone; Jeffers et al.; Jeffers et al. in view of Examiner's Official Notice; Campbell et al. in view of Zaboklicki, DE 2,904,891; and Jeffers et al. in view of Zaboklicki.

26-28. All claims are subject by the Office to an administrative requirement based on the nonstatutory double patenting rejection based on a judicially created doctrine preventing the unjustified or improper timewise extension of the "right to exclude" granted by a patent and to prevent possible harassment by multiple assignees.

29. Claims 56-181 are rejected under the judicially created doctrine of obviousness-type double patenting as being unpatentable over any single claim or combination of claims of all of Applicants' claims in Applicants' issued U.S. patents: 4,694,490, 4,704,725, 4,965,825, 5,109,414, 5,233,654 and 5,335,277.

30. Claims 56-181 are rejected under the judicially created doctrine of obviousness-type double patenting as being unpatentable over any single claim or combination of claims of all of Applicants' claims in Applicants' issued U.S. patents: 4,694,490, 4,704,725, 4,965,825, 5,109,414, 5,233,654 and 5,335,277, further in view of each combination of art described within the Office Action.

B. Summary of Amendments

Claim 56 has been amended to recite:

“least a first request in order to enable content to be displayed,” to further clarify the language in view of Applicants' disclosure;

“to present said locally generated image,” to correct the antecedent basis problem;
and

“said locally generated image with said image from said remote video source,” to further clarify the language in view of Applicants' disclosure.

Claim 58 has been amended to recite, “detecting an instruct signal received at said interactive video apparatus,” to further clarify the language in view of Applicants' disclosure.

Claim 60 has been amended to recite, “further comprising processing an identifier,” to further clarify the language in view of Applicants' disclosure.

Claim 65 has been amended to recite, "wherein said interactive video apparatus includes a computer," to further clarify the language in view of Applicants' disclosure.

Claim 66 has been amended to recite, "organizing is performed by a processor," to further clarify the language in view of Applicants' disclosure.

Claim 67 has been amended to recite, "further comprising the step of storing," to further clarify the language in view of Applicants' disclosure.

Claim 69 has been amended to recite, "a computer which stores said data," to correct an antecedent basis problem.

Claim 72 has been amended to recite, "said remote video source," to correct an antecedent basis problem.

Claim 73 has been amended to recite, "remote video source," to correct an antecedent basis problem.

Claim 75 has been amended to recite, "said one of said first and second transmitter stations," to correct an antecedent basis problem.

Claim 76 has been amended to recite:

"receiving at least a portion of said first video image at said one of said first and second transmitter stations," to correct an antecedent basis problem and further clarify the language in view of Applicants' disclosure; and

"said first video image to said at least one receiver station," to correct an antecedent basis problem.

Claim 77 has been amended to recite, “downloadable processor instructions and identification data in respect of said downloadable processor instructions,” to correct an antecedent basis problem, and

“a signal containing at said first video image” to further clarify the language with respect to Applicants’ disclosure.

Claim 78 has been amended to recite, “downloadable processor instructions programs said processor (i) to output video one of simultaneously and sequentially with said video presentation, (ii) to process a subscriber reaction to content of said information transmission,” to correct an antecedent basis problem and further clarify the language with respect to Applicants’ disclosure.

Claim 79 has been amended to recite, “wherein said target processor,” deleting the second occurrence of the word “said.”

Claim 81 has been amended to recite, “wherein said at least one control signal comprises information which, at the remote intermediate transmitter station, identifies a first portion of an information transmission that contains said video, said method further comprising the step of: transmitting a second control signal which, at said remote intermediate transmitter station, controls the communication of at least a second portion of said information transmission” to further clarify the language in view of Applicants’ specification.

Claim 82 has been amended to recite, “transmitting one of said at least one control signal before transmitting said video to said remote intermediate transmitter station,” to further clarify the language in view of Applicants’ specification.

Claim 86 has been amended to recite, "processes said first discrete signal," deleting the typographical error "to."

Claim 88 has been amended to recite:

"a receiver in said transmitter station," to correct an antecedent basis problem; and
"said receiver in the transmitter station to a memory location," to further clarify the language in view of Applicants' disclosure.

Claim 93 has been amended to recite:

"at least one first discrete signal," to correct an antecedent basis problem; and
"passing at least one processor instruction from or within said at least one processor," to further clarify the language in view of Applicants' disclosure.

Claim 96 has been amended to recite, "said generated image to replace said only said portion of said video image," to correct an antecedent basis problem.

Claim 102 has been amended to recite, "said method further including the step of: communicating a request for information to a remote station," to further clarify the language in view of Applicants' disclosure.

Claim 104 has been amended to recite, "processing user input based on said receiver specific control signal," to correct an antecedent basis problem.

Claim 105 has been amended to recite, "said only said portion of said video image," to correct an antecedent basis problem and the typographical error of "and" between "video image."

Claim 106 has been amended to recite:

“wherein said step of outputting said video presentation includes,” and
“said video image and said generated image,” wherein both occurrences were
made to further clarify the language in view of Applicants’ disclosure.

Claim 107 has been amended to recite, “said video image,” to correct an
antecedent basis problem.

Claim 109 has been amended to recite, “to replace said only said portion of said
video image,” to correct an antecedent basis problem.

Claim 112 has been amended to recite, “at least one of (i),” to correct a
typographical error misplacing “of.”

Claim 113 has been amended to recite, “said portion of said video presentation,”
to correct an antecedent basis problem.

Claim 116 has been amended to recite:

“a remote transmitter station,” to correct an antecedent basis problem; and
“said at least one processor instruction,” to delete the second occurrence of the
word “said.”

Claim 117 has been amended to recite, “and a portion of said video presentation,”
to correct an antecedent basis problem.

Claim 122 has been amended to recite:

“where at least one of said plurality of receiver stations;”

“display only a portion of said video presentation;” and

and deleting, “said method further comprising the step of transmitting said data,”

wherein all amendments correct an antecedent basis problem.

Claim 123 has been amended to recite:

“said at least one of said plurality of receiver stations;”

“at least one control signal;”

“at least one instruct signal;” and

“at least one transmitter,” wherein all amendments correct an antecedent basis problem.

Claim 124 has been amended to recite:

“a video image and only a portion of said video presentation,” and

“receiving said video image at said at least one of said first remote transmitter station and a second remote transmitter station,” to correct an antecedent basis problem.

Claim 126 has been amended to recite, “wherein said at least one transmitter transmits said at least one instruct signal, said at least one first discrete signal, and said at least one control signal in a data transmission,” to correct antecedent basis problems.

Claim 127 has been amended to recite:

“detecting said at least one second signal,” and

“said at least one of said first remote transmitter station and said second remote transmitter station,” to correct antecedent basis problems.

Claim 128 has been amended to recite, "detecting said at least one second signal," to correct an antecedent basis problem.

Claim 129 has been amended to recite, "transmitting to said at least one of said plurality of receiver stations at least one datum that designates one of a time and a channel of transmission of said instruct signal," to further clarify the language in view of Applicants' disclosure.

Claim 130 has been amended to recite, "at least one instruct signal," to correct an antecedent basis problem.

Claim 131 has been amended to recite:

"at least one instruct signal," and

"at least one control signal," to correct antecedent basis problems.

Claim 132 has been amended to recite:

"said at least one first remote transmitter station and said second remote transmitter station," and

"at least one transmitter," to correct antecedent basis problems.

Claim 133 has been amended to recite, "said at least one first remote transmitter station and said second remote transmitter station," to correct an antecedent basis problem.

Claim 134 has been amended to recite, "said at least one first remote transmitter station and said second remote transmitter station," to correct an antecedent basis problem.

Claim 135 has been amended to recite:

“said at least one first remote transmitter station and said second remote transmitter station,” to correct an antecedent basis problem; and

“controlling said switch to communicate to said one of a memory and a recorder at least one second signal,” to further clarify the language in view of Applicants’ disclosure.

Claim 139 has been amended to recite, “to communicate at least one second signal,” to further clarify the language in view of Applicants’ disclosure.

Claim 140 has been amended to recite, “to communicate said instruct signal from a tuner to said processor,” to further clarify the language in view of Applicants’ disclosure.

Claim 141 has been amended to recite:

“a television monitor which displays said video presentation;” and

“transmitting said series of computer generated images,” wherein both correct an antecedent basis problem.

Claim 142 has been amended to recite:

“passing at least one processor instruction from or within said at least one processor,” to clarify the language in view of Applicants’ disclosure, and

“based on said step of passing,” to delete the second occurrence of “said.”

Claim 143 has been amended to recite, "at least one first discrete signal" and "at least one second discrete signal." to further clarify the language in view of Applicants' disclosure.

Claim 147 has been amended to recite, "at least one first discrete signal," to further clarify the language in view of Applicants' disclosure.

Claim 149 has been amended to recite, "at least one first discrete signal," to further clarify the language in view of Applicants' disclosure.

Claim 150 has been amended to recite, "receiver station," correcting the typographical error of "receiving."

Claim 151 has been amended to recite, "at least one first discrete signal" and "said video image," to correct antecedent basis problems.

Claim 152 has been amended to recite, "said first remote transmitter station," corrects an antecedent basis problem.

Claim 153 has been amended to recite, "video image and said local image of said video presentation," to further clarify the language in view of Applicants' disclosure.

Claim 155 has been amended to recite, "said downloadable processor instructions program said processor generate information contained in said video presentation or to process user input or to respond to said user input," to further clarify the language in view of Applicants' disclosure.

Claim 158 has been amended to recite, "which operates at said remote intermediate transmitter station," to correct an antecedent basis problem.

Claim 161 has been amended to recite, "to control one or more of a plurality of selective transfer devices," to further clarify the language in view of Applicants' disclosure.

Claim 162 has been amended to recite:

"said plurality of discrete signals;" and

"said video image," wherein both changes correct an antecedent basis problem.

Claim 164 has been amended to recite, "said code concurrently," to correct an antecedent basis problem.

Claim 165 has been amended to recite, "in a television or other electronic transmission," to further clarify the language in view of Applicants' disclosure.

Claim 166 has been amended to recite, "said receiver in said transmitter station to a memory location," to further clarify the language in view of Applicants' disclosure.

Claim 171 has been amended to recite:

"said video monitor," to correct an antecedent basis problem; and

"only a portion," to correct a typographical error by replacing "one."

Claim 175 has been amended to recite:

“transmitting, from an origination transmitter, a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and, before a specific time, said one or more control signals,” and,

“one of (i) said first completed full-screen video graphic image and said at least one discrete signal, and, (ii) said at least one processor instruction,” to further clarify the language in view of Applicants’ disclosure.

C. Statement of Patentable Novelty under 37 C.F.R. § 1.111

Applicants submit that the independent claims as amended include the following limitations that are not found in the prior art. These limitations show patentable novelty in view of the state of the art disclosed by the references cited and the objections made.

Claim 56

...receiving from said remote data source said data to serve as a basis for displaying said video presentation;
processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and
displaying said locally generated image at said video output device in conjunction with said image from said remote video source.

Claim 75

...said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image;
receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor

instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;

receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation.

Claim 80

...an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video.

Claim 84

...wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction; and

wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video.

Claim 93

...organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;

passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;

responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;

generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and

outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.

Claim 110

...wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data; and

receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction.

Claim 116

...wherein said one receiver station displays video received at said one receiver station from a remote transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction; and receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal.

Claim 123

...wherein one of a code and an identifier is operative at said one of said plurality of receiver stations to designate one of a second image and a device;

receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at said at least one of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image; and

said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said at least one of said plurality of receiver stations and is operative to cause

said at least one instruct signal to be effective at said at least one of said plurality of receiver stations.

Claim 142

...organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;

passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;

generating only a portion of said video image based on said step of responding to said at least one processor instruction; and

outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.

Claim 143

...organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;

generating a signal based on said processor instructions; and

outputting at least a portion of said video presentation based on said generated signal.

Claim 152

...receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor

instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image.

Claim 157

...an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image.

Claim 162

...said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image.

Claim 167

...organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image.

Claim 171

...at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image;

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station; and

wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image.

Claim 175

...at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image; and

one or more control signals operate at said remote intermediate transmitter station to control communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, and said at least one processor instruction.

Claim 177

...one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image.

Claim 179

...organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image.

D. Response to Interview Summary of Jan. 6, 2000

The Examiner included an Interview Summary with the Office Action. The Interview Summary purports to record a telephonic interview between Examiner William Luther and Applicants' representative Thomas Scott, Jr. on January 6, 2000. Applicants' representatives had numerous contacts with PTO personnel regarding the deficiencies of the Office Action mailed November 19, 1999. However, to ensure an accurate record, Applicants note that Thomas Scott, Jr. did not participate in a telephonic interview with Examiner Luther on January 6, 2000.

E. Response to Objection to the Specification

1. Amendment of March 4, 1999

The Office Action states, "the amendment filed 3/4/99 is objected to under 35 U.S.C. 132 because it introduces new matter into the disclosure." (Office Action at 6-7.) The amendment changes page 37, lines 23-25, of the specification to read:

Controller, 39, 44, or 47, is preprogrammed to receive [units] words of signal information, to assemble said [units] words into signal [words] units that subscriber station apparatus can receive and process, and to transfer said [words] units to said apparatus.

(Additions underlined, deletions bracketed.)

Applicants submit that this amendment corrects an inadvertent error made in preparation of the specification as filed. The amendment includes no new matter. Applicants respectfully request that the Examiner withdraw the objection for the following reasons.

The amended language describes that aspect of the invention in which signal words are received and assembled into signal units. The assembly of signal words into signal units is described consistently throughout the specification in the manner effected by the amendment. As the amendment merely clarifies the disclosure, the amendment introduces no new matter.

The specification as filed, on page 14, lines 23-25, describes, "discrete words . . . that receiver apparatus must assemble in order to receive one complete instruction." A signal unit is defined as "one complete signal instruction." (Spec. at 14 ll. 26-27.) Thus, words must be assembled to create a signal unit. The specification consistently discloses that signal words are received and assembled into signal units.

Further, the specification consistently refers to signal words as the basic information block from which other information units are formed. The specification at page 65, lines 34-35, states; "Each message is composed in a whole number of signal words." "Said information consists of a series of discrete signal words." (Spec. at 70 ll.

28-29.) “[S]aid given signal word is an EOFs WORD and may be part of an end of file signal.” (Spec. at 71 ll. 5-7.) “[T]o detect those particular uninterrupted series of EOFs WORDs that constitute end of file signals.” (Spec. at 74 ll. 11-12.) “For example, end of file signals could include the signal word preceding said uninterrupted sequence.” (Spec. at 82 ll. 23-25.) Signal words are formed into commands and other signals throughout the specification.

In the recent Office Action, the sentence on page 15, lines 4-6, of the specification is relied upon as evidence that the amendment is new matter. (Office Action at 8.) The sentence reads, “Signal words may contain parts of signal units, whole signal units, or groups of partial or whole signal units or combinations.” This statement simply describes the circumstance in which a higher level word could contain a lower level unit. Obviously, this statement does not contradict the prior statement that discrete *words must* be assembled to obtain a signal *unit*. As signal words are disclosed as being assembled into signal units, the amendment cannot contain new matter, regardless of the other variations disclosed in the specification. The statement relied upon by the Examiner actually supports the conclusion that the amendment does not introduce new matter.

In *Personalized Media Communications, L.L.C. v. International Trade Commission*, No. 97-1532 (Fed. Cir. Jan. 7, 1999), the U.S. Court of Appeals for the Federal Circuit construed claim 35 in U.S. Patent No. 5,335,277 (the ‘277 patent). The ‘277 patent issued to Applicants on August 2, 1994, from a specification identical to the specification filed in the instant application. In construing the claims of the ‘277 patent, the Court concluded that the prosecution history of the ‘277 patent did not prevent the term “information of a selected television unit” from reading on channel and time information. The Court thus addressed the meaning of the term “selected television program unit.” The Court noted that “a selected program unit” is a particular television program, such as Wall Street Week. There is no merit to the Examiner’s assertion that the amendment to the specification alters the meaning of the term “a selected program

unit” as determined by the Court. (Office Action at 8-10.) The Court did not address the meaning of the terms “signal unit” or “signal word.” No reasoning set forth by the Court conflicts with Applicants’ assertion that the specification discloses that signal units are assembled from signal words. The citations from *Personalized Media Communications* contained in the recent Office Action are irrelevant to issue of new matter introduced by the amendment.

Applicants maintain that the amendment to the specification filed March 4, 1999, corrects an obvious error in the specification as originally filed. The amended language describes the assembly of signal words into signal units. The assembly of signal words into signal unit is described at page 14, lines 23-27, of the specification. Therefore, the amendment does not include new matter. Accordingly, Applicants request that the objection to the specification be withdrawn.

2. Amendment of June 6, 1995

The Examiner addresses the preliminary amendment filed June 5, 1995. (Office Action at 11.) The Examiner states, “paper no. 3 incorporated by reference it’s parent ‘in it[’]s entirety’ on 6/5/99 so that the portion of ‘in it[’]s entirety’ that is not common to the ’87 C.I.P. is considered . . . new matter to the instant disclosure.” The Examiner errs in his conclusion since the document attempted to be incorporated by reference is an *identical* specification to the specification of the instant application. Per the amendment above, the incorporation by reference language has been deleted to eliminate this error. See Part G.1.a)(2)(b) below for Applicants’ explanation of how the instant specification includes the subject matter of the disclosure of Applicants’ Application No. 317,510, filed November 3, 1981, issued as U.S. Patent No. 4,694,490.

F. Response to Allegation of Defective Oath/Declaration

The Examiner asserts that the oath or declaration is defective. (Office Action at 13.) The Examiner asserts that the instant application is a continuation-in-part of

This Page Blank (uspto)

Application No. 113,329, filed August 30, 1993. Thus, the Examiner requires a new oath or declaration that acknowledges the duty to disclose to the Office all information known to Applicants to be material to patentability which occurred between the filing date of the prior application and the filing date of the instant application. Applicants note that the disclosure as filed June 6, 1995, is identical to the disclosure of Application No. 113,329. Applicants properly filed the instant application under the provisions of 37 C.F.R. § 1.60 as in effect on June 6, 1995. Rule 60 provided conditions under which an Applicant may omit signing a new oath or declaration in a continuation application. Applicants respectfully submit that they have fully complied with the provisions of Rule 60 as in effect upon filing of the instant application. Accordingly, Applicants request that the requirement for a new oath or declaration be withdrawn. Notwithstanding the above, should the Examiner maintain the requirement to file a new oath or declaration, Applicants respectfully request that the requirement be held in abeyance until allowable subject matter is indicated as provided under 37 C.F.R. § 1.111.

G. Response to Rejections under 35 U.S.C. § 112

1. Response to Rejections under §112, first paragraph

a) Response to Written Description Rejections

**(1) The Office Action Fails to Establish a Prima Facie
Rejection Under the Written Description Requirement of
35 U.S.C. § 112**

In the Office Action, the Examiner rejects claims 56-181 under 35 U.S.C. § 112, first paragraph for incorporating subject matter not described in the specification as filed in such a manner as to reasonably convey to one skilled in the relevant art that the inventors, at the time the application was filed, were possessed of the claimed invention. (Office Action at 13-14.) Applicants firmly believe that the instant specification and respective priority documents, all of which are substantially identical, each describe the

subject matter of the pending claims. Thus, in Applicants' view, the pending claims fully comply with the requirements of the first paragraph of 35 U.S.C. § 112. Accordingly, Applicants respectfully request the withdrawal of the rejections of claims 56-181 under 35 U.S.C. § 112, first paragraph.

The Examiner notes that the instant specification does not include the exact words and phrases of the disclosure of Applicants' parent Application No. 317,510 (the '81 disclosure.) (Office Action at 15.) The Examiner argues that since Applicants successfully assert that the '81 disclosure supports the pending claims and the '81 disclosure is not duplicated verbatim in the instant specification then it follows that the instant specification does not support the pending claims. The Examiner assumes that the subject matter in the '81 disclosure that is not duplicated verbatim within the instant specification is omitted from the instant specification. This assumption is incorrect. Applicants maintain that, although the '81 disclosure is not included in identical words in the instant specification, the subject matter of the '81 disclosure is specifically included in the instant specification.

"The function of the description requirement is to ensure that the inventor had possession, as of the filing date of the application relied on, of the specific subject matter later claimed by him." *In re Wertheim*, 541 F.2d 257, 262, 191 U.S.P.Q. 90, 96 (C.C.P.A. 1976). Applicants rely on the filing date of November 3, 1981. On this date, Applicants filed Application No. 317,510, now issued as U.S. Patent No. 4,694,490 (the '490 patent). The specification of the '490 patent (the '81 disclosure) clearly demonstrates that Applicants had possession of the subject matter presently claimed.

"[T]he PTO has the initial burden of presenting evidence or reasons why persons skilled in the art would not recognize in the disclosure a description of the invention defined by the claims." *Id.* at 263, 191 U.S.P.Q. at 97. The Examiner has failed to meet this burden. The record of the prosecution of the instant application fails to include any reasons why persons skilled in the art would not recognize from the specification that

Applicants invented the invention defined by the pending claims. The Examiner merely states, at page 15 of the Office Action, that the "instant '571 disclosure has not been found to describe the alleged '81 support ' . . . in such full, clear, concise, and exact terms . . . ' as is required under the law of 35 U.S.C. 112 1st paragraph." At pages 20-79 of the Office Action, the Examiner also provides a list of claim phrases that are deemed to lack support. This list includes practically all phrases from nearly all the pending claims and amounts to an unsubstantiated assertion that the pending claims as a whole are unsupported under the written description requirement of 35 U.S.C. § 112, first paragraph. The Examiner has failed to present evidence or reasons why persons skilled in the art would not recognize in the disclosure a description of the invention defined by the claims.

The outstanding rejection under the written description requirement is merely a blanket, unsupported statement that the pending claims fail to meet the requirements of 35 U.S.C. § 112, first paragraph. Because the Examiner includes no reasons for the rejection, the only manner for Applicants to respond is to exhaustively demonstrate where each and every limitation in the pending claims is found in the specification without regard to how clearly the specification may show each limitation to those skilled in the art. In fact, the Examiner explicitly requests Applicants to perform a five-step process including making "a 'one-to-one correspondence' between 'the original '87 C.I.P. disclosed terms' and 'pending claim terms.' " (Office Action at 19.) Applicants find this request unprecedented and unreasonable. However in order to advance the prosecution of the instant application, Applicants submit herewith, Appendix A, reciting specification support for each claim limitation to the instant specification.

The Examiner also asserts at page 20 of the Office Action, "[the] pending claims are found to recite 'terms whose definitions are different/diverse' between the '81 disclosure and the '87 disclosure." No support is provided for this assertion. "[I]t is suggested that Applicants consider providing an enumerate list of definitions for each

pending claims which recites 'terms whose definitions are difference/diverse' between the '81 and '87 C.I.P. disclosures for the purpose of satisfying 112 1st paragraph's requirement." (Office Action at 20.) Applicants assert that the claims do not include terms whose definitions are diverse between the '81 disclosure and the instant specification. The Examiner cites as examples the terms such as "programming," "instruct," "instruction," "information," and "data." However, the Examiner provides no details of different or diverse use of these terms. Applicants note that the term "programming" is addressed in the context of 35 U.S.C. § 112, second paragraph, in Part 2.c) below. Applicants maintain that the specification includes an adequate written description of the claimed invention that shows Applicants' possession of the invention. The Examiners unsupported assertion that claim terms are defined differently in the '81 disclosure and the '87 disclosure fails to provide evidence or reasons why persons skilled in the art would not recognize in the disclosure a description of the invention defined by the claims.

**(2) The PTO's Requested Process for Successfully Traversing
the Written Description Rejection is Not Required by 35
U.S.C. § 112**

The Examiner suggests, at page 19 of the Office Action, that Applicants perform a five-step process to successfully traverse the written description rejections. The process is as follows:

- 1) make a 'one-to-one correspondence' between 'the originally disclosed '87 C.I.P. terms' and 'pending claim terms';
- 2) make a 'one-to-one correspondence' between 'the originally disclosed '87 C.I.P. steps within a single '87 C.I.P. embodiment' and 'pending claim steps';
- 3) make a 'one-to-one correspondence' between 'the originally disclosed '87 C.I.P. processes' and 'the pending claim processes in the manner such processes are claimed' so that the 'steps' of 2) and the terms of are recognized therein;
- 4) repeat steps 1) through 3) with the '81 disclosure;

5) reconcile the steps 1) through 4) with each element of the *alleged pending claim support* when there is a discrepancy.

This request reaches beyond the obligations mandated by the written description requirement of 35 U.S.C. § 112. If the Examiner carries the burden of making out a *prima facie* case of unpatentability, only then does the burden of coming forward with evidence or argument shift to the Applicants. *In re Alton*, 76 F3d 1168, 37 U.S.P.Q.2d 1578, 1583. To overcome a *prima facie* case, an applicant must show that the invention as claimed is adequately described to one skilled in the art. *Id.* 37 U.S.P.Q.2d at 1583-84. Accordingly, Applicants need not comply with the process suggested by the Examiner in order to comply with the requirements of 35 U.S.C. § 112. Applicants respectfully submit that the extensive support provided in Appendix A demonstrates that the pending claims are supported by the specification as prescribed by the law of 35 U.S.C § 112, first paragraph. With respect to the suggested five-step process, Applicants submit that at the very least, Appendix A provides a correspondence between the written description and the pending claim terms, steps, and processes.

(a) 35 U.S.C. § 112 Includes No Requirement That the Entire Support for Each Individual Claim Must Come From Within a Single Detailed Example Described in the Specification

The second step of the five-step process suggested by the Examiner to overcome the written description rejection requires that the support for each claim come from a single embodiment described in the specification. Each manifestation of Applicants' claimed invention, regardless of how the manifestation may be described in the specification, is a single embodiment of the invention. Thus, the specific support provided for each claim is by definition from within a single embodiment.

Applicants acknowledge that there are numerous embodiments of the presently claimed invention described in the specification. Applicants' specification is a single cohesive document with each successive section and example *incorporating, extending*

and developing the preceding disclosure. The various disclosures, examples, and subsystems disclosed within the specification are clearly intended to be integrated into general working systems, methods and apparatus. Applicants' specification is very carefully constructed to provide clear and unequivocal contextual relationship between the various inventive concepts, processes and apparatus that Applicants disclose.

At the outset, Applicants focus on the importance of *integrating* functionalities and state:

It is the object of this invention to unlock this great potential in the fullest measure by means of an *integrated system* of programming communication that joins together all these capacities most efficiently.

(Spec. at 3 ll. 30-33)(emphasis added).

In "Background of the Invention" (Spec. at 1-11), Applicants list a multitude of problems and limitations in the prior art for which this integrated system provides valuable solutions. Applicants *also introduce focal opportunity*:

Today great potential exists for combining the capacity of broadcast communications media to convey ideas with the capacity of computers to process and output user specific information. One such combination would provide a new radio-based or broadcast print medium with the capacity for conveying general information to large audiences--e.g., "Stock prices rose today in heavy trading,"--with information of specific relevance to each particular user in the audience--e.g., "but the value of your stock portfolio went down." (Hereinafter, the new media that result from such combinations are called "combined" media.)

Unlocking this potential is desirable because these new media will add substantial richness and variety to the communication of ideas, information and entertainment. Understanding complex subjects and making informed decisions will become easier.

(Spec. at 2 ll. 8-24.)

Applicants explicitly acknowledge that to succeed in the fullest measure means solving many technical problems as well as providing for a broad spectrum of subscriber information demands and equipment capacities:

To unlock this potential fully requires means and methods for combining and controlling receiver systems that are now separate--television and computers, radio and computers, broadcast print and computers, television and computers and broadcast print, etc.

But it requires much more.

To unlock this potential fully requires *a system with efficient capacity* for satisfying the demands of subscribers who have *little receiver apparatus and simple information demands* as well as subscribers who have *extensive apparatus and complex demands*. It requires capacity for transmitting and organizing vastly more information and programming than any one-channel transmission system can possibly convey at one time. It requires capacity for controlling intermediate transmission stations that receive information and programming from many sources and for organizing the information and programming and retransmitting the information and programming so as to make the use of the information and programming at ultimate receiver stations as efficient as possible.

(Spec. at 2 l. 25 through p. 3 l. 8)(emphasis added).

To disclose how the integrated system overcomes the identified limitations, solves the problems, and realizes this potential fully, requires ***step-by-step teaching*** of separate elements – methods as well as apparatus – of Applicants' disclosed system. At each new step, the ***contextual relationship*** of the new teaching to earlier teachings ***is explicitly stated***. Applicants highlight below how this step-by-step teaching carries the relationships of the various separate elements throughout the disclosure.

(i) **“One Combined Medium” (pages 19-28)**

In a section, (Spec. at 19-28), entitled “One Combined Medium,” (Spec. at i l. 16 and p. 19 l. 5), which focuses on the subscriber station of Fig.1, Applicants begin by teaching “a *video/computer* combined medium,” (Spec. at 19 l. 6)(emphasis added). A local image – Fig. 1A (*See* Spec. at 25 ll. 9-14) – is provided at the subscriber station and combined with a remotely supplied video image – Fig. 1B (*See* Spec. at 25 ll. 30-33) – in order to deliver a combined image of Fig 1C (*See* Spec. at 26 ll. 8-15). (Simultaneously, user specific local images are provided at other subscriber station and combined with the remotely supplied video image – (*see*, specification at page 26 lines 16-19.)

(As an example of Applicants' step-by-step teaching approach, not until a section entitled "Audio Overlays and Other Overlays," which begins on page 463, are Applicants prepared to focus on Fig. 7D and teach "a radio/computer combined medium," (Spec. at 464 l. 6), or teach "a broadcast print and computer combined medium," (Spec. at 466 l. 20), or focus on Fig. 7E and teach "the full combined medium of television and computers," (Spec. at 468 ll. 10-11).

In the "One Combined Medium" section, Applicants disclose concepts of "a combining operation" and "synchronization". For example: "subscriber station apparatus ... execute *a combining operation in synchronization....*" (Spec. at 26 ll. 21-22)(emphasis added).

Applicants also teach *order of operations*. For example, one operation. (Spec. at 24 ll. 5-27), may provide the local image—Fig. 1A—at the subscriber station; a different operation, (Spec. at 26 ll. 4-11), may deliver the combined image—Fig. 1C. ("One Combined Medium" also discloses that a third operation, (Spec. at 27 ll. 3-7), may terminate delivery of the combined image.)

More broadly, in "One Combined Medium" Applicants teach *important concepts regarding instructions* and, *most importantly, timing*. For example:

Decoder, 203, is **preprogrammed** to detect digital information Microcomputer, 205, is **preprogrammed** ... to respond ... to *instruction signals* embedded in the ... programming transmission.

(Spec. at 21 ll. 14-24)(emphasis added).

In said series in full--and in any one or more subsequent series of instructions--*particular instructions are separated*, as may be required, *by time periods when no instruction* that controls the microcomputer, 205, of any station *is transmitted* which periods allow sufficient time for the microcomputer, 205, of each and every subscriber station *to complete functions* controlled by previously transmitted instructions and commence waiting for a subsequent instruction, in a waiting fashion well known in the art, before receiving a *subsequent instruction*.

(Spec. at 22 ll. 9-18)(emphasis added).

... *an instruction ... causes* subscriber station apparatus to execute a combining operation in *synchronization*

(Spec. at 26 ll. 21-22)(emphasis added).

In addition, personalized programming is displayed *only when* it is of specific relevance to the conventional television programming of said combined medium. In the example, each subscriber views a graphic presentation of his own portfolio performance information *as soon as* it becomes specifically relevant to graphic information of the performance of the market as a whole. Prior to its time of specific relevance, no personalized information is displayed (despite the fact that said graphic information of the performance of the market as a whole is displayed). And said personalized information is displayed *only for so long as* it remains specifically relevant. *As soon as* its specific relevance terminates, its display terminates.

(Spec. at 27 ll. 21-33)(emphasis added).

In the "One Combined Medium" section, Applicants demarcate a critical type of instruction with a definition.

Hereinafter, an instruction ... that causes subscriber station apparatus to execute a combining operation ... is called a "combining synch command."

(Spec. at 26 ll. 20-23)(emphasis added).

Furthermore, in "One Combined Medium," Applicants teach a temporal relationship of combining synch commands that have specific functionalities. A ***first combining synch command***, (See Spec. at 24 ll. 5-27 and p. 26 ll. 23-28), causes the local image—Fig. 1A—to be provided at the subscriber station. A ***second combining synch command***, (See Spec. at 26 ll. 1-8 and 20-23), causes display of the combined image—Fig. 1C. (Furthermore, a ***third combining synch command***, (See Spec. at 27 ll. 3-7), terminates display of the combined image.) In their step-by-step teachings, Applicants ***provide clear contextual pertinence of subsequent teachings by making explicit reference to*** the "One Combined Medium" disclosure, and especially by ***establishing the temporal relationships of subsequent teachings*** to the Fig. 1C combining and the functionalities provided by these combining synch commands.

(ii) **“The Signal Processor” through “The Normal Transmission Location” (pages 28-86) and “The Preferred Configuration of Controller, 39, and SPAM-Controller, 205C.” (pages 156-162)**

In the specification at pages 28-86 and pages 156-162, Applicants teach apparatus and signaling techniques that are *used throughout the remainder of Applicants’ disclosure*. Applicants teach Signal Processor, (Spec. at 28-34 and Fig.1); Signal Decoder, (Spec. at 34-38 and Figs.2A-2C); and Signal Processor System, (Fig.2D), apparatus. *Applicants also teach in detail the controller* (Spec. at 156-162 and Fig.3A) *apparatus of Signal Decoders* (e.g., controller, 39, in Fig. 2A). Applicants teach signaling techniques in sections entitled “The Composition of Signal Information ... Commands, Information Segments, and Padding Bits,” (Spec. at 43-49), The Organization of Message Streams ... Messages, Cadence Information, and End of File Signals,” (Spec. at 59-69), “Detecting End of File Signals,” (Spec. at 69-84), and “The Normal Transmission Location,” (Spec. at 84-86).

(iii) **“Operating Signal Processor Systems ... Introduction” through “Operating Signal Processor Systems ... Signal Record Transfer” (pages 86-278)**

At specification pages 86-278, Applicants teach methods of operating the signal processing apparatus of pages 28-86 and 156-162 explicitly within the context of the “One Combined Medium” disclosure. For example:

Five examples illustrate methods of operating signal processing system apparatus. Each focuses on subscriber stations where the signal processor system of Fig. 2D and *the combined medium apparatus of Fig. 1* share apparatus and operate in common. Fig. 3 shows one such subscriber station.

(Spec. at 86 l. 32 through p. 87 l. 2)(emphasis added).

All five examples describe signal processing variations that relate to *the Fig. 1C combining of “One Combined Medium.”*

(Spec. 87 ll. 30-32)(emphasis added).

Each example focuses on the processing of the three signal messages of the *Fig. 1C combining*. The information of said messages include three combining synch

commands and one program instruction set. The first message is of the information associated with the *first combining synch command*. Said first command has a "01" header, an execution segment, and a meter-monitor segment of six fields. Said command is followed by an information segment that contains said program instruction set, and said information segment is followed by an end of file signal. Said first command addresses URS microcomputers, 205, and causes said computers, 205, to load and run the program instruction set transmitted in the information segment.

(Spec. at 89 ll. 3-16)(emphasis added).

The second message is of the information associated with the *second combining synch command*.

(Spec. at 90 ll. 4-5)(emphasis added).

The third message is of the information associated with the *third combining synch command*.

(Spec. at 90 ll. 28-29)(emphasis added).

Repeatedly throughout each of the five examples, reference is made to pertinent "One Combined Medium" disclosures. For example, in Example #1, (Spec. at 93-143),

Applicants state:

OPERATING SIGNAL PROCESSOR SYSTEMS ... EXAMPLE #1.

The first example elaborates on the Fig. 1C combining described above in "One Combined Medium" and focuses on the operation of decoder, 203, SPAM-controller, 205C, and microcomputer, 205, on the execution of controlled functions, and on the the use of cadence information to organize signal processing. The example begins as divider, 4, starts to transfer to decoder, 203, in its outputted composite video transmission, the embedded binary information of the first message.

(Spec. at 93 ll. 20-29.)

As described in "One Combined Medium" above, loading and running said program instruction set causes microcomputer, 205, (and URS microcomputers, 205, at other subscriber stations) to place appropriate Fig. 1A image information at particular video RAM.

(Spec. at 107 ll. 20-24.)

In the foregoing fashion and as described in "One Combined Medium" above, said transferred information of the second combining synch command causes microcomputer, 205, to combine the programming of Fig. 1A and of Fig. 1B and

transmit said combined programming to monitor, 202M, where Fig. 1C is displayed.

(Spec. at 125 l. 31 through p. 126 l. 1.)

Fig. 3 (which is the combination of the apparatus of Figs. 1 and 2D (*See Spec. at 86 l. 32 et seq.*)) and Fig. 3A (the controller in the decoders 30 and 203 in Fig. 3, (*See Spec. at 156 l. 18 et seq.*)) depict the receiver station at which all five examples occur. Example #1 discloses in detail transfer of SPAM messages to addressed apparatus at the receiver station as well as the execution of controlled functions in response to the messages. Example #2 discloses selective decryption of content of the SPAM message stream at decryptor 10 of signal processor 200. Example #3 discloses the creation of signal records at signal processor 200 based on monitoring information contained in the message stream that delivers the Fig. 1C image. Example #4 discloses functioning of the Fig. 3A controller 39 in decoder 203, including selective decryption at decryptor 39K and additional processing of the message stream content to create signal records. Example #5 discloses the functioning of signal processor 200 components (e.g., 6, 1, 2, 3, 30 and 40) to gather data on the availability of programming (see, for example, page 269 line 6).

Pages of the specification 271-278, state: "In examples #3, #4, and #5, the transmission of SPAM signal information causes signal processor, 200, to transfer signal record information by telephone to remote station computers," (Spec. at 271 l. 33 *et seq.*) and teach this process in detail.

(iv) "Regulating the Reception and Use of Programming ... including Example #6" and "... Example #7" (pages 278-312) as well as "... More on Example #7 ... Combining ... Automatically to the Computer System ..." (pages 427-447)

At pages 278-312 of the specification, Applicants teach methods of governing the reception and use of programming and relate to, for example, "digital ... television transmissions," (*See Spec. at 279 l. 14*). Example #6 discloses a variant of the type of decryption techniques disclosed in examples #2 and #4 to regulate the use of control

signal, in particular. Focusing on the receiver station of Fig. 4, (*See Spec.* at 286 l. 6 through p. 288 l. 20), example #7 discloses a multistage process of selectively decrypting digital components (video and audio) of a “television signal,” (*See Spec.* at 288 ll. 32-33). The multistage process includes selective transfer, *e.g.*, by tuning or switching, (*Spec.* at 295 ll. 6-30). At pages 427-447, additional regulating concepts are taught which are variants to the disclosure of pages 287-312, and which rely on disclosures (*e.g.*, intermediate transmitter station automation, (*Spec.* at 324-390)) which occur in the specification between pages 312 and 427.

Just like every one of examples #1-#5, examples #6 and #7 (*Spec.* at 287-312 and 427-447) are disclosed within the context of the “Wall Street Week” program. With respect to example #6, see, for example, page 281 lines 7-9. With respect to example #7, see, for example, page 289 lines 12-27 and page 429 lines 26-33. The examples also disclosed functionally and temporally with respect to earlier disclosures such as in “One Combined Medium” at pages 19-28 (*e.g.*, *Spec.* at 311 ll. 10-16 and p. 447 ll. 8-14).

(v) “Monitoring Receiver Station Reception and Operation” (pages 312-324)

At pages 312-324 of the specification, Applicants teach methods of monitoring the reception and operation of a receiver station using Fig. 5. Fig. 5 shows an extended system of monitoring decoder, controlled by signal processor 200, each monitoring an associated device and communicating monitor information to signal processor 200. This disclosure is also set within the context of the “Wall Street Week” program (*See Spec.* at 322 ll. 26-27), references Fig.1B (*Spec.* at 322 l. 35), and cites previously defined portions of example #3, which concern monitoring (*see Spec.* at 322 ll. 30-35, p. 174 ll. 21-23, and p. 190 ll. 14-16).

(vi) **“Automating Intermediate Transmission Stations”
(pages 324-390) including “Example #8” (pages 340-354)**

At pages 324-390 of the specification, Applicants teach automation of intermediate stations. The teachings relate to forms of programming that include, but are not limited to, television, radio, and data and that apply to all manner of broadcast and cablecast operations (*see* Spec. at 324 ll. 11-17, p. 339 l. 9 through p. 340 l. 10, and p. 389 l. 14 through p. 390 l. 11). Figs. 6A-B illustrate Applicants’ teachings in the setting of a cable television system. Generally speaking, apparatus of Figs. 6A-B are described at page 324 line 18 through page 328 line 17 and page 337 lines 1-24, and the basic methods of operation of the station (e.g., operating according to a complete programming schedule) are disclosed at page 325 line 17 through page 326 line 18 and page 328 line 8 through page 331 line 16. Organizing units of prerecorded programming (e.g., to play according to schedule) is disclosed at page 331 line 17 through page 334 line 6. Playing according to schedule is disclosed at page 334 line 7 through page 336 line 35. Monitoring station operations is disclosed, *inter alia*, (e.g., to provide auditable proof-of-performance) at page 337 line 25 through page 339 line 8. In their teachings of organizing, playing and monitoring, Applicants introduce exemplary programming, including **program unit Q** which is a specific focus of later disclosures in Applicants’ specification. Applicants teach the subject matter of pages 324-390 following pages 86-324 to make clear that the earlier teachings apply at intermediate transmission stations as well as end user stations, (e.g., Spec. at 339 l. 29 through p. 340 l. 10 and p. 389 l. 31 through p. 390 l. 11).

In example #8, Applicants teach a distribution station, such as a satellite uplink, which transmits control signals and units of programming, such as television spot commercials, to a plurality of automated intermediate transmission stations as taught at pages 324-340 (Spec. at 340 l. 13 through p. 345 l. 28). The intermediate transmission stations receive the control signals, (e.g., Spec. at 342 l. 18 through p. 343 l. 17 and p.

344 ll. 28-32), and the programming, and store and retransmit selected exemplary television spot commercials – **most focally program unit Q**, (e.g., Spec. at 343 ll. 5-17, p. 351 l. 27 through p. 352 l. 30, and p. 353 ll. 6-28), with each intermediate station operating independently and retransmitting its selected exemplary commercial(s) at different times and in different channels (Spec. at 343 l. 5 through p. 344 l. 22 and p. 345 l. 29 through p. 354 l. 3). The intermediate stations automatically retain and communicate proof-of-performance records to one or more remote auditing stations, (see Spec. at 341 ll. 11-15 and p. 352 l. 18 through p. 354 l. 3).

(vii) **Examples #9 and #10 (pages 354-390 & 469-516):
“Automating Intermediate ... Station Combined
Medium Operations” (pages 354-374 of Example #9)
and “Network Control of Intermediate Generating
and Embedding” (pages 374-390 of Example #10)**

In examples #9 and #10, at pages 354-374 of the specification for example #9 and pages 374-390 for example #10, Applicants teach automation of an intermediate station in creation and transmission of combined medium programming (“of the same sort as ‘Wall Street Week’” at page 355 lines 1-2). At pages 469-516, Applicants teach the corresponding operations of a plurality of end user stations to which the intermediate station transmits the programming so created. Both examples focus on **Program unit Q** (see Spec. at 354 l. 35 through p. 355 l. 14, p. 374 l. 29 through p. 375 l. 12, p. 469 ll. 1-2, and p. 478 ll. 23-26). In each example, Applicants teach a sequence of messages and carefully **name each message in the sequence with a name that ties together the transmitter functions of pages 354-390 and the corresponding end user station functions of pages 469-516 unambiguously.** (Appendix D, a Glossary of Defined Terms, is included herewith identifying certain terms as defined by their use in the instant specification and including, in its final pages, a list messages pertaining to each Example.) For example, the “program-instruction-set message (#9)” is defined at page 371 lines 17-19 and transmitted at page 372 lines 4-6; the “program-instruction-set

message (#10)” is defined at page 385 lines 14-16 and transmitted at page 386 lines 12-14: the “program-instruction-set message (#10)” is received at the end user station(s) at page 484 lines 5-14; and at page 514 lines 8-13, 17 and 23-24 Applicants teach that the “program-instruction-set message (#9)” “[causes] the same functioning” at the end user station(s) as the “program-instruction-set message (#10)”. Some of the other messages in the sequence are named at page 372 lines 20-35, page 387 lines 19-31, page 490 lines 24-34, page 492 lines 1-11, page 495 lines 1-10, etc., and page 514 lines 8-31.

At pages 354-374 in example #9, Applicants teach local **origination**, (Spec. at 374 l. 6 and p. 368 ll. 3-4), of combined medium programming at an automated transmitter station (which is also an intermediate transmission station). **Program unit Q**, which is delivered to and handled at the intermediate station according to the teachings of pages 324-354, (Spec. at 355 ll. 15-17), is disclosed as television-based combined medium programming, (Spec. at 354 l. 35 through p. 355 l. 14), that contains embedded signals, (e.g., Spec. at 356 l. 9 through p. 358 l. 21, p. 367 ll. 30-33, p. 369 ll. 4-6, and p. 372 ll. 22-35). As one example of the creation of programming, at pages 359 line 14 through page 365 line 21, Applicants teach automation of the intermediate station to create a set of instructions (called “PROGRAM.EXE” at page 365 line 8 and defined as the “program-instruction-set of Q” at page 365 lines 18-21) and to transmit the instructions, (Spec. at 371 l. 11 through p. 372 l. 6), in a “program-instruction-set message,” (Spec. at 371 ll. 17-19 and p. 372 ll. 4-6).

At pages 374-390 in example #10, Applicants teach **network origination** (Spec. at 374 ll. 20-31) of combined medium programming and focus especially on the creation of programming *in the network* at automated intermediate stations as well as at an origination station. **Program unit Q** in example #10 is the same program unit Q as in example #10 (Spec. at 375 ll. 7-8). In example #10 Applicants disclose the same creation of programming as in example #9. For example, page 377 line 4 through page 382 line 14 corresponds to page 358 line 26 through page 366 line 18; “PROGRAM.EXE”

appears at page 379 line 24, page 380 line 18, and page 382 line 3; definitions of the “program-instruction-set of Q.1” and “program-instruction-set of Q.2” occur at page 378 lines 23-28 and at page 380 lines 20-24 respectively; and generated instructions are transmitted at page 385 line 9 through page 386 line 14 in a “program-instruction-set message.” But in contrast to example #9 which focuses on origination at just one transmitter station, in example #10 Applicants teach a plurality of automated intermediate station operating in parallel under control of a network origination station to generate and transmit control instructions messages (*see* Spec. at 59 ll. 29-33) to different end user stations. Furthermore, Applicants teach that the control instructions differ from each other (e.g., the PROGRAM.EXE files in the messages (Spec. at 484 ll. 9-10 and 17-18) differ (Spec. at 379 ll. 5-31 and p. 380 ll. 7-20)).

The end user station functionalities of examples #9 and #10 are disclosed at pages 469-516. Applicants teach a series of combined medium outputs (e.g., Spec. at 491 ll. 10-16 and p. 506 ll. 17-21) in response to the transmitted control instructions or “messages” (Spec. at 484 ll. 5-18, p. 485 ll. 14-18, p. 490 l. 24 through p. 491 l. 16, and p. 505 l. 32 through p. 506 l. 21). Furthermore, the information outputted in the combined medium outputs differs from end user station end user station (Spec. at 491 ll. 10-29 and p. 506 ll. 17-31). Applicants also teach in examples #9 and #10 *other functionalities, such a viewer interactivity and interactivity with stations remote from the end user stations*, that are discussed more fully below.

(viii) Automating Ultimate Receiver Stations (pages 390-427) ... Regulating Station Environment (pages 396-406) ... Coordinating a Stereo Simulcast (pages 406-419) ... Receiving Selected Programming (419-427)

Focusing on Fig. 7, Applicants teach, at pages 390-396 of the specification, apparatus and functionalities of an end user station including computing, signal processing (e.g. Figs. 2-2D), switching, decrypting, etc., in addition to receivers, storage

devices, and various speaker and display devices. On page 396 is additional disclosure associated with the preferred controller. 39. taught at pages 156-162. At pages 396-406, Applicants disclosure concepts associated with broadcast/cablecast control of end receiver station heating/cooling and mechanical systems as well as interactivity associated with, for example, utilities meter reading. At pages 406-419, Applicants teach coordinating separate systems under broadcast/cablecast control – in this case, controlling devices associated with television and radio to present a stereo simulcast – as well as monitoring the devices in order to provide records of the performance of the stereo simulcast and of other presentations at the end user station to a remote data collection station. At pages 419-427, Applicants teach storing identifiers (e.g., of the stocks in a stock portfolio) and controlling the receiver station (e.g., tuning cable converter 222 at page 423 lines 11-13) to receive identified news at to process the news (e.g., Spec. at 425 ll. 30-34) according to pre-entered instructions of a user.

(ix) More Disclosure in the Context of “Wall Street Week” (pages 427-469)

Having taught basic concepts of apparatus and automation of ultimate receiver stations, Applicants teach more advanced concepts within the context of “Wall Street Week” and its many attendant earlier teachings. Applicants’ objective, in so doing, is to **teach how the various teachings, attendant to “Wall Street Week”, relate to each other.**

(a) More on Example #7 (pages 427-447)

At pages 427-447 of the specification, Applicants elaborate on the earlier “Regulating Systems” (Spec. at 288 l. 22) teachings of example #7 (Spec at 288-312), which are summarized in section (iv) above. Applicants teach the network described in “One Combined Medium” (Spec. at 20 l. 28 through p. 21 l. 4) as a **self structuring, parallel processing computing system.** This teaching follows Applicants teaching of

“Automating Intermediate Transmission Stations” (Spec. at 324 l. 7 and pp. 324-390) in order to **elaborate on intermediate transmission station** (e.g., see references to Fig. 6 at page 429 line 29 and page 325 lines 15-16) **automation** within the context of example #7 (e.g., Spec. at 429 l. 26 through p. 435 l. 15) and the teachings attendant to “Wall Street Week” generally. Applicants teach the selective processing of incoming programming in accordance pre-stored “program-unit-of-interest information” (e.g., Spec. at 428 ll. 21-26) that enables different viewer stations to handle differently (e.g., store/display, automatically authorize purchase of) the “Wall Street Week” programming. Applicants teach storage of programming (Spec. at 445 ll. 27-32) that includes (e.g., Fig. 1C) the locally provided information (e.g., Fig. 1A) combined with the remotely supplied information (e.g., Fig. 1B).

**(b) Controlling Combined Medium
Operations (pages 447-457)**

At pages 447-457 of the specification, Applicants teach the functioning of “One Combined Medium” (Spec. at 19-28) within the context (e.g., Spec. at 451 ll. 1-3) of functions that (i) precede (Spec. at 447 l. 26 through p. 451 l. 11) the beginning of the “One Combined Medium” programming (i.e., “Wall Street Week”) and (ii) follow (Spec. at 451 l. 4 through p. 457 l. 10) the display of Fig. 1C. Applicants teach **providing and updating viewer data (e.g., stock portfolio data) before** the start of, for example, “Wall Street Week” and controlling viewer stations to generate and combine into the “One Combined Medium” programming **a series of local images with each image combined within its specific time interval of relevance**. Applicants also teach **error correction techniques for controlling viewer station computers that function incorrectly or inefficiently**.

**(c) Transmitting Program Instructions Sets
(pages 457-463)**

Having taught generation of more than one image, inefficiency, and error correction, Applicants teach methods, at pages 457-463, for timely provision of software for controlling the generating and combining of local images (e.g., Fig. 1A) into the “One Combined Medium” programming. These include varying size of the bandwidth in which the software is located, as well as the location(s) and the timing pattern(s) in which the software is transmitted.

(x) Audio Overlays and Other Overlays (pages 463-468)

Focusing on Fig. 7D, Applicants teach a radio combined medium at pages 464-466 of the specification, including local selection at a radio receiver station of user specific audio and insertion of the selected audio into radio programming supplied from a remote radio transmitter. Applicants teach a broadcast print combined medium at pages 466-468, including local selection at a broadcast print receiver station of user specific text and insertion of the selected text into broadcast print programming supplied from a remote transmitter. Focusing on Fig. 7E, Applicants teach at page 468 a television combined medium that includes customized audio as well as customized video.

**(xi) Examples #9 and #10 Continued – Viewer/Listener
Station Functionalities (pages 469-516)**

To teach the viewer/listener station processing of **program unit Q** in examples #9 and #10 (*see* section (vii) above), Applicants focus on the “ultimate receiver station” (defined at page 40 line 35 through page 41 line 1) of Fig. 7 (e.g., Spec. at 390 ll. 30-31 and p. 470 l. 9). Having taught the concepts summarized in section (x) above, Applicants can teach receiver stations interconnecting “apparatus ... in the fashion of Fig. 7E” (Spec. at 480 ll. 16-17). In this environment, Applicants teach local interactions (e.g., by humans at page 471 lines 6-18 and page 508 line 19 through page 509 line, and by equipment at, for example, page 484 lines 7-18 and page 509 line 35 through page 511

line 22) result in interaction between local station and remote station equipment (*see* Spec. at 509 l. 35 through p. 510 l. 4). Drawing on virtually every previous teaching, Applicants disclose at pages 469-516 generation of a series of outputs (*e.g.*, Spec. at 485 ll. 14-18) that include video (*e.g.*, Spec. at 491 ll. 10-29), audio (Spec. at 491 l. 30 through p. 493 l. 22), and print (Spec. at 496 l. 3 through p. 499 l. 3). Applicants also disclose error correction, as summarized in the section above, at page 514 line 32 through page 516 line 13. Furthermore, Applicants disclose at page 514 lines 8-31 that the viewer/listener stations perform substantively identically in examples #9 and #10.

(xii) Preprogramming Receiver Station Operating Systems (pages 516-532) and The Preferred SPAM Header (pages 532-533)

At pages 516-532 of the specification, Applicants teach one master control station (*e.g.*, Spec. at 518 ll. 17-26) transmitting operating system instructions to and programming transmitter and receiver station widely dispersed over a geographic area with the operating systems. Each station to be programmed selects those operating system instructions that apply to its particular type and version of reprogrammable device(s) (*e.g.*, Spec. at 522-524), routes the instructions to memory of the reprogrammable device(s), and commences operating under control of the operating system instructions. At pages 532-533, Applicants further focus on the desirability of flexibility for system expansion and teach that the preferred SPAM header is one byte in length.

(xiii) The General Case ... Summary Example #11 (pages 533-557)

While Applicants could summarize their disclosure by simply stating that each method and feature of their disclosed "unified system" (Spec. at 533 l. 24) could be combined with every other method and feature (on its face an apparent tautology), they choose, instead, to provide one final example which explicitly relies on the entirety of

foregoing disclosure. In example #11, programming is distributed in a time cycling fashion (*e.g.*, Spec. at 536 l. 11 *et seq.* and p. 556 ll. 12-14) from a European master control station via satellite (Spec. at 536 ll. 4-6) to national intermediate transmission stations (Spec. at 534 ll. 26-31) which transmit to local intermediate transmission station (Spec. at 535 ll. 18-22) which, in turn, transmit to ultimate receiver stations (Spec. at 534 ll. 1-4) where programming is displayed (*e.g.*, Spec. at 552 ll. 20-30) and information is communicated responsively (*e.g.*, Spec. at 555 ll. 14-29) back to the European master control station and the national and local intermediate stations (Spec. at 555 l. 26 through p. 556 l. 9).

The European master control station controls the national intermediate stations (*e.g.*, Spec. at 541 l. 29 through p. 542 l. 2 and p. 543 ll. 20-29) to control the local intermediate stations (*e.g.*, Spec. at 544 l. 23 through p. 545 l. 11) to control the ultimate receiver stations (*e.g.*, Spec. at 547 ll. 19-26 and p. 548 ll. 1-6). User specific information is generated at each ultimate receiver station (*e.g.*, Spec. at 548 ll. 18-22 and p. 550 ll. 30-31), stored at each ultimate receiver station (*e.g.*, Spec. at 551 ll. 11-14), explained in combined medium output (Spec. at 552 ll. 17-30), and communicated to the European master control station and the national and local intermediate stations (Spec. at 555 l. 26 through p. 556 l. 9). At points in the disclosed example #11 cycle where functions are described in general, reference is made to earlier sections of the specification that teach the detail of how the function is performed. For example, at page 537 lines 6-17, the European master control station is explicitly disclosed as preprogramming the national and local intermediate stations and the ultimate receiver stations in the fashion summarized in the above section.

(xiv) Conclusion

As demonstrated above, within the specification, many embodiments of the claimed invention are disclosed. Each manifestation of an apparatus or method that

includes the subject matter defined by the instant claims is a *single* embodiment of Applicants' invention. Such a single embodiment of Applicants' invention may have elements or steps that are described in detail in various separate sections of the instant specification. Every embodiment of the instant invention that is described by the specification as a whole is a *single* embodiment of the instant invention that provides support under the written description requirement.

It appears, however, that what the Examiner intends to request is that Applicants provide support for every limitation of an individual claim from within a single one of the detailed enumerated examples listed in the specification. In other words, the Examiner requests that the support provided for all the limitations of an individual claim be contiguous or proximate within *only a portion* of the specification, rather than the specification as a whole. The written description requirement of 35 U.S.C. § 112 does not mandate such contiguous or proximate descriptions of each element or step of every individual claim.

"To fulfill the written description requirement, a patent specification must describe an invention and do so in sufficient detail that one skilled in the art can clearly conclude that the 'inventor invented the claimed invention.'" *Regents of University of California v. Eli Lilly and Co.*, 119 F.3d 1559, 43 U.S.P.Q.2d 1398, 1404 (Fed. Cir. 1997)(quoting *Lockwood v. American Airlines*, 107 F.3d 1565, 41 U.S.P.Q.2d 1398, 1405 (Fed. Cir. 1997)). Applicants submit that one of ordinary skill in the art would determine that the inventors possessed the claimed invention by recognizing that the embodiments indicated in Appendix A are described in the specification. Since, for the reasons discussed above, one of ordinary skill in the art would recognize that the specification is a single cohesive document containing many descriptions of methods and apparatus included in general integrated systems, there is no reason that the entire support for each individual claim must come from within a single detailed enumerated example described in the specification. However in order to advance the prosecution of the instant

application, Applicants have selected embodiments for inclusion in Appendix A that include elements and steps described primarily in a single enumerated example of the specification.

(b) The Subject Matter in the '81 Disclosure is Specifically Included In the Instant Specification

In the Office Action, the fourth step of the suggested five-step process to overcome the written description requirement, requests that steps 1 through 3 be repeated with respect to the '81 disclosure. Applicants recognize that they must convey that they were in possession of the invention as of the effective filing date of November 3, 1981. Applicants also recognize that the claim of priority under 35 U.S.C. § 120 requires that the previously filed application disclose the invention in the manner provided by the first paragraph of 35 U.S.C. § 112. Accordingly, throughout the prosecution of the pending claims, Applicants have provided support based on the application filed November 3, 1981. Applicants also submit herewith, in Appendix A, support for each claim limitation from the application filed November 3, 1981. Applicants respectfully submit that the detailed support provided in Appendix A demonstrates full compliance with the written description requirement of 35 U.S.C. § 112, first paragraph, and the related requirement of 35 U.S.C. § 120. Additionally, Applicants submit Appendix C herewith, to provide a correlation between the 1981 priority specification (as referenced the column and line numbers of Applicants' U.S. Pat. No. 4,694,490) and the instant specification.

In the Office Action at page 5, the Examiner seeks an explanation for how the '81 disclosure can be considered the specification support. The subject matter in the '81 disclosure is clearly included in the instant specification. Applicants respectfully assert that one skilled in the art, upon recognizing a description of the invention in the '81 disclosure, would readily recognize a description of the invention in the instant specification. The Examiner concludes in the Office Action, at page 15, "that instant '571 disclosure has not been found to describe the alleged '81 support." No support is

provided for this conclusion. The Examiner merely states at page 6 of the Office Action that the previously provided support does not cite the sentences, paragraphs, or passages of the instant specification. Applicants submit that the support provided in Appendix A demonstrates that the instant specification describes the subject matter that is originally disclosed in the '81 application and is presently claimed.

The Examiner states, in the Office Action, at page 16, "It is fact that Applicants have failed to maintain continuity of 'the entire '81 (Nov. 3, 1981), disclosure' when they filed the continuation-in-part document of '87 C.I.P. (Sept. 11, 1987)." Applicants disagree. The Examiner also states, "Applicants have acknowledged, in interview, that they did not include *the alleged pending claim support* either 'specifically' or by 'expressly incorporating it by reference' when originally making the '87 C.I.P. disclosure" (Office Action at 15.) *The alleged pending claim support* refers to the descriptions of the various embodiments of the claimed invention cited from the '81 disclosure during the prosecution of the pending claims. Applicants clarify that the instant specification does not included a verbatim duplication of the '81 disclosure. However, Applicants maintain that the subject matter in the '81 disclosure is specifically included in the instant specification. Neither 35 U.S.C. § 112 nor 35 U.S.C. § 120 requires that the parent application be incorporated into the pending application either by reference or by verbatim repetition. "In order to determine whether a prior application meets the 'written description' requirement with respect to later-filed claims, the prior application need not describe the claimed subject matter in exactly the same terms as used in the claims; it must simply indicate to persons skilled in the art that as of the earlier date the applicant had invented the what is now claimed." *Eiselstein v. Frank*, 52 F.3d 1035, 34 U.S.P.Q.2d 1467, 1470 (Fed. Cir. 1995)(citation omitted)(quoting *Vas-Cath v. Mahurkar*, 935 F.2d 1555, 1561, 19 U.S.P.Q.2d 1111, 1116 (Fed. Cir. 1991)). Applicants respectfully submit that the support cited in Appendix A demonstrates that the '81

disclosure indicates to persons skilled in the art that as of November 3, 1981, Applicants had invented what is now claimed.

The Examiner rejects claims 56-181 under 35 U.S.C. § 112, first paragraph. (Office Action at page 97.) The Examiner asserts that "all independent claims . . . and those claims depending therefrom, seem to mix and match '81 and '87 disclosed embodiments when respective entire claim trees are considered." The Examiner suggests that Applicants specifically enumerate which claim trees are considered directed toward an '81 embodiment and which are directed towards an '87 embodiment. As discussed above, Applicants respectfully submit that each pending claim defines an invention that has embodiments described in both the application originally filed November 3, 1981, and the instant specification. Applicants assert that the support provided herewith in Appendix A demonstrates that the claims are directed to an invention supported by both the application as originally filed November 3, 1981, *and* the instant specification.

**(c) 35 U.S.C. § 112 Includes No Requirement That
Identical Embodiments of the Invention be Described in
Both a Parent Application and a Subsequent
Application Claiming Priority Therefrom**

In the Office Action, the fifth step of the five-step process suggested to overcome the written description rejection requests Applicants to reconcile steps 1 through 4 when there is a discrepancy. In the Office Action, at pages 5-6, the following is also asserted:

Applicants have provided the PTO with conflicting pending claim support within the bodies of the following papers:

- Appendix B [of the Office Action];
- Appendices C I thru C XXIV [of the Office Action] (216 pages);
- instant paper 12 filed 8/6/97;
- instant paper 18 filed 9/18/98;
- instant paper no. 22 filed 3/4/99;
- application 08/471,024 paper no. 12 filed 10/3/97;
- application 08/471,024 paper no. 17 filed 10/14/98;
- application 08/468,641 filed 9/8/97; and
- application 08/468,641 paper no. 16 filed 5/18/98.

The Examiner also states in the Office Action, at page 80, that the support for the claims "is replete with discrepancies." No discrepancies are specifically identified by the Examiner. It is unclear to what conflicts and discrepancies the Examiner refers. Applicants have reviewed the previously provided support and have failed to identify significant conflicts or discrepancies. Applicants request that any conflicts or discrepancies perceived by the Examiner be specified so that Applicants may properly address this issue. However, in view of the step by step approach suggested to show support, it appears that the Examiner expects Applicants to rely on only one embodiment of the claimed invention to demonstrate support for the pending claims throughout the prosecution of the pending claims. The written description requirement of 35 U.S.C. § 112 includes no such mandate.

As discussed above, there are many embodiments of the claimed invention disclosed in the specification in such full, clear, concise, and exact terms that one skilled in the art would clearly conclude that Applicants invented the claimed invention as of the effective filing date of the application. There is no conflict or discrepancy for Applicants to refer to one embodiment at one point during the prosecution of the instant application and to refer to another embodiment at a different point. Applicants may independently rely on various embodiments of the claimed invention to demonstrate support under the written description requirement. Likewise, there is no requirement in either 35 U.S.C. § 112 or 35 U.S.C. § 120 that identical embodiments of the invention be described in both a parent application and subsequent application claiming priority therefrom. As noted above, "the prior application need not describe the claimed subject matter in exactly the same terms as used in the claims; it must simply indicate to persons skilled in the art that as of the earlier date the applicant had invented the what is now claimed." *Eiselstein v. Frank*, 52 F.3d 1035, 34 U.S.P.Q.2d 1467, 1470 (Fed. Cir. 1995)(citation omitted)(quoting *Vas-Cath v. Mahurkar*, 935 F.2d 1555, 1561, 19 U.S.P.Q.2d 1111, 1116 (Fed. Cir. 1991)). "[I]psis verbis disclosure is not necessary to satisfy the written

description requirement of section 112. Instead, the disclosure need only reasonably convey to persons skilled in the art that the inventor had possession of the subject matter in question.” *Fujikawa v. Wattonasin*, 39 U.S.P.Q.2d 1895, 1904 (Fed. Cir. 1996)(quoting *In re Edwards*, 568 F.2d 1349, 1351-52, 196 U.S.P.Q 465, 467 (C.C.P.A. 1978)). Applicants may rely on different embodiments at different times to show that the disclosure conveys to those skilled in the art that Applicants had possession of the claimed subject matter. Applicants respectfully submit that such use of multiple embodiments is permissible to demonstrate compliance with the written description requirement of 35 U.S.C. § 112. However, where clarity permits, Applicants have selected similar embodiments from both the '81 disclosure and the instant specification for inclusion in Appendix A to demonstrate compliance with the written description requirement.

(3) Conclusion

The Examiner has failed to establish a *prima facie* rejection under the written description requirement of 35 U.S.C. § 112, first paragraph, because no reasons are given as to why one skilled in the art would not consider the description sufficient. The Examiner suggests a five-step process to overcome the applied written description rejection. The five-step process implies that the support provided for all the limitations of an individual claim must be contiguous or proximate within a single enumerated example of the specification. The five-step process also implies only one embodiment of Applicants' invention may be used to demonstrate support for each individual claim. The written description requirement of 35 U.S.C. § 112 includes neither of these requirements. The Examiner also asserts that there is a lack of continuity between the disclosure in the application filed November 3, 1981 and the instant specification. Applicants maintain that, although the '81 disclosure is not included in identical words in the instant specification, the subject matter of the '81 disclosure is included in the instant

specification. Furthermore to demonstrate support for the instant claims, submitted herewith, in Appendix A, are tables demonstrating support for each claim from both the '81 disclosure and the instant specification. In view of the above arguments and Appendix A, Applicants respectfully request that the rejection under the written description requirement of 35 U.S.C. § 112, first paragraph be withdrawn.

b) The Specification Enables One Skilled in the Art to Make and Use the Invention

The Examiner rejects the pending claims under the enablement requirement of 35 U.S.C. § 112, first paragraph. (Office Action at 80.) The Examiner concludes that the handling/transmission of "digital television signals" is not enabled by the specification. (Office Action at 85.) The Examiner also concludes that "data" could not be processed in the same manner as television and radio programming units. (Office Action at 90.) However, these conclusions are not directed specifically to the invention claimed by the presently pending claims.

The test for enablement is whether one reasonably skilled in the art could make or use the invention from the disclosure in the application coupled with information known in the art without undue experimentation. *United States v. Telectronics, Inc.*, 857 F.2d 778, 785, 8 U.S.P.Q.2d 1217, 1223 (Fed. Cir. 1988). The invention is defined by the claims presented in the instant application. The Examiner concludes that the terms "digital" and "data" are not enabled. The Examiner fails to consider how these terms define Applicants' invention in the instant claims. The Examiner has failed to include any analysis of whether any particular claim is supported by the disclosure. The PTO bears the initial burden of setting forth a reasonable explanation as to why it believes that the scope of protection provided by each claim is not adequately enabled by the description of the invention provided in the specification of the application. *In re Wright*, 999 F.2d 1557, 27 U.S.P.Q.2d 1510, 1513 (Fed. Cir. 1993) The Examiner has failed to consider the scope of protection provided by the claims in his analysis under the

enablement requirement. Therefore, the Examiner has failed to establish a *prima facie* rejection under the enablement requirement of 35 U.S.C. § 112, first paragraph.

The Examiner also rejects claims 56-181 ostensibly under the enablement requirement of 35 U.S.C. § 112, first paragraph, because he asserts that the claims seem to mix and match '81 and '87 disclosed embodiments. (Office Action at 97.) The Examiner suggests Applicants enumerate which claim trees are directed toward an '81 embodiment and which are directed toward an '87 embodiment. In Part a)(2)(b) above, Applicants have fully addressed this ground of rejection in the context of the written description requirement. Applicants maintain that each pending claim defines an invention that has embodiments described in both the application originally filed November 3, 1981, and the instant specification. The Examiner has failed to determine that one reasonably skilled in the art could not make or use the invention by the conclusion that the claims "seem to mix and match '81 and '87 disclosed embodiments." Therefore, the Examiner has failed to establish a proper rejection under the enablement requirement of 35 U.S.C. § 112, first paragraph.

(1) "Digital" is Enabled by the Specification

Claims 61 and 63 stand rejected under 35 U.S.C. § 112, first paragraph, because the Examiner alleges these claims contain subject matter which was not described in the specification in such a way as to enable one skilled in the art to which it pertains, or with which it is most nearly connected, to make and/or use the invention. (Office Action at 80.) The Examiner asserts the specification fails to disclose the manner in which digital television signals are formatted and processed. The Examiner acknowledges that the transmission of digital television signals was known in the art. The rejection is based on the assertion that the transmission of digital television signals was not interchangeable with the transmission of analog television signals and the Examiner's conclusion that Applicants' disclosure assumes that they are interchangeable. This reasoning is an

insufficient basis for the rejection of claims 61 and 63 for at least two reasons. First, the Examiner's discussion of the transmission and formatting of digital television signals is not directed to the scope of claims 61 and 63. Second, the means needed to format and transmit digital television signals in a manner compatible with all the methods and apparatus disclosed in the specification was known by those skilled in the art.

Claim 61 is fully enabled by the specification. Claim 61 is dependant from claim 60. Claim 60 sets forth an identifier. Claim 61 sets forth that the identifier identifies, *inter alia*, digital programming. The Examiner's discussion directed to the term "digital television signals" fails to address an identifier that identifies digital programming. Thus, the Examiner has failed to establish a reasonable basis to question the enablement of an identifier that identifies digital programming.

Claim 63 is fully enabled by the specification. Claim 63 sets forth that an interactive video apparatus communicates with a remote data source via a digital information channel. The Examiner's discussion directed to the term "digital television signals" fails to address a digital information channel. Thus, the Examiner has failed to establish a reasonable basis to question the enablement of a digital information channel.

Notwithstanding the above arguments, Applicants recognize that the invention defined by claims 61 and 63 is compatible with the use of digital television signals. The handling and transmission of digital television signals in a manner compatible with the methods described in the specification were well know to those skilled in the art as of the filing date of the instant application. The Examiner requests Applicants to submit references which show that the means needed to format and transmit "digital television signals" were known to those skilled in the art. Applicants submit that U.S. Patent No. 3,906,480 issued on September 16, 1975 to Schwartz et al. discloses the means needed to format and transmit "digital television signals" in a manner compatible with the methods described in the specification. Schwartz et al. discloses decomposing vectors to be displayed into elemental vector segments that are *encoded* as vector symbols. Schwartz

et al. further discloses that the system has the capability of storing each vector in a compacted (i.e. compressed) form while retaining its attributes and identity in storage. Applicants contend that the specification discloses the usage of digital data in a television signal similar to that which is disclosed in Schwartz et al. The means needed to format and transmit digital television signals in this manner were well known to those skilled in the art as of the filing date of this application.

The Examiner has failed to construe the claims in his analysis under the enablement requirement. The Examiner directs his analysis to the term "digital television signals," but fails to demonstrate how this analysis applies to claims 61 and 63. Furthermore, means compatible with Applicants' disclosure of formatting and transmitting digital television signals were well known in the art, contrary to the Examiner's assertion. For at least these reasons, Applicants respectfully request the withdrawal of the rejection of claims 61 and 63 under the enablement requirement of 35 U.S.C. § 112, first paragraph.

(2) "Data" is Enabled by the Specification

Claims 56, 58-59, 62-65, 69, 75, 77, 79, 81, 85, 101, 109-110, 112, 115, 122, 126, 129, 141, 146, 151, 152 and all claims depending therefrom stand rejected under 35 U.S.C. § 112, first paragraph, because the Examiner alleges these claims contain subject matter which was not described in the specification in such a way as to enable one skilled in the art to which it pertains, or with which it is most nearly connected, to make and/or use the invention. (Office Action at 87.) The Examiner notes that the specification discloses that SPAM messages can be embedded within the "normal locations" of "other media" such as broadcast data or print. The Examiner also notes that the specification discloses that print or data information is transmitted within SPAM messages. Applicants acknowledge the disclosure from line 6 of page 85 through line 11 of page 86 of the instant specification, which describes that SPAM signals may accompany

conventional print or data programming. It is unclear to what specific disclosure the Examiner refers by the specific citations recited on pages 87, 88, and in the footnote on page 89 of the Office Action. The Examiner asserts that these disclosures are so contradictory that one of ordinary skill in the art would need to resort to undue experimentation to practice the invention. (Office Action at 88.) Applicants firmly assert that a thorough reading of the specification shows that the disclosure is in no way contradictory with respect to the term "data."

Applicants disclose the use of SPAM signals to control and coordinate a wide variety of subscriber stations. (Spec. at 40.) The information of SPAM signals includes data, computer program instructions, and commands. (Spec. at 41 ll. 20-21.) One typical example of the composition of a SPAM signal is shown in Figure 2E. (Spec. at 44.) The specification clearly discloses that SPAM signals may include information segments. (Spec. at 44 l. 11.) Program instruction sets, intermediate generation sets, other computer information, and data may all be transmitted in information segments. (Spec. at 53 l. 34 through p. 54 l. 2.) Applicants disclose that SPAM signals can be embedded in many different locations in electronic transmissions. (Spec. at 85 ll. 6-7.) In broadcast and data communications transmissions, SPAM signals can accompany conventional print or data programming in the conventional transmission stream. (Spec. at 85 ll. 20-23.) More precisely, the conventional print or data information may be transmitted in an information segment of a SPAM signal. (Spec. at 86 ll. 1-11.) Thus, SPAM signals can be included in broadcast print and data communication transmissions. Also, conventional data information can be transmitted in an information segment of a SPAM signal. There is no conflict in this disclosure. Any person skilled in the art would be enabled to use SPAM signals to control and coordinate a subscriber station through a broadcast data communication transmission by reading the instant specification. After thoroughly reading the specification any person skilled in the art would require no undue experimentation to practice Applicants' claimed invention.

The Examiner asserts that Applicants' disclosure did not describe a system or method which formatted, transmitted, received, processed, or displayed data program units under control of associated SPAM messages because data program units were actually transmitted with the SPAM messages. (Office Action at 89.) The Examiner extends this conclusion to hold that the disclosure fails to set forth the means or steps needed to make or use systems in which data is manipulated in the same manner as described for television and radio television program units. (Office Action at 90.) The Examiner's conclusion fails to follow from the stated facts. Data program units transmitted with SPAM signals can be manipulated under the control of the associated SPAM signal. The fact that data are disclosed as transmitted in the information segment of SPAM signals in no way conflicts with disclosed control of such transmissions through the use of the SPAM signals.

Furthermore, at most the Examiner's conclusion applies to data communication transmissions that are controlled through the use of SPAM signals accompanying data programming. However, the Examiner makes no attempt to construe the claims to determine how this rejection applies to the scope of each claim. Assuming *arguendo* that the Examiner's reasoning is correct, every use of the term data does not violate the enablement requirement of 35 U.S.C. § 112. Applicants recognize that the pending claims set forth an invention that may be used with broadcast print or data communications transmissions. However, Applicants submit that the instant rejection does not directly apply to the following claim limitations:

In claim 56, receiving data from a remote data source and processing the data.

In claim 63, communicating with a remote data source via a digital information channel.

In claim 69, a computer which stores data.

In claim 75, 110, and 152, a processor instruction having at a receiver station a target processor to process data.

In claim 77, identification data embedded in a non-visible portion of a signal containing a video image.

In claim 79, generating a portion of a video image by processing data.

In claim 81, a code or datum which identifies data that is described or promoted in video.

In claim 85, identification data embedded in a signal containing video.

In claim 101, communicating data to a remote site.

In claim 109, wherein a processor acts by processing data.

In claim 112, a signal that includes identification data.

In claim 115, transmitting data.

In claim 129, a datum that specifies data associated with an instruct signal.

In claim 146, a generated signal containing receiver specific data.

In claim 151, communicating data to a remote station.

Applicants also note that the following amendments may obviate this rejection:

Claims 58 and 62 have been amended to delete the reference the remote data source.

Claim 64 has been amended to delete the reference to first data and second data.

Claim 65 has been amended to delete the reference to second data.

Claims 122 and 141 have been amended to delete the step of transmitting said data.

For at least the above reasons, Applicants submit that the subject matter defined by claims 56, 58-59, 62-65, 69, 75, 77, 79, 81, 85, 101, 109-110, 112, 115, 122, 126, 129, 141, 146, 151, and 152 is described in the specification in such a way to enable any person skilled the art to make or use Applicants' invention. Accordingly, Applicants respectfully request that the rejection of these claims be withdrawn.

**c) The Best Mode of Practicing the Claimed Invention
Contemplated by Applicants is Disclosed in the Specification**

Claims 56-181 stand rejected under 35 U.S.C. § 112, first paragraph, because it is asserted that the best mode contemplated by the inventor has not been disclosed. (Office Action at 90-91.) The first paragraph of 35 U.S.C. § 112 provides that the specification "shall set forth the best mode contemplated by the inventor of carrying out his invention." A two step inquiry is used to determine if the best mode requirement is met. *Chemcast Corp. v. Arco Industries Corp.*, 913 F.2d 923, 16 U.S.P.Q.2d 1033,1036 (Fed. Cir. 1990) First, the Examiner must determine whether, at the time Applicants filed their patent application, they knew of a mode of practicing the claimed invention that they considered to be better than any other. *Id.* Second, the Examiner must determine whether the

disclosure is adequate to enable one skilled in the art to practice the best mode, if one was known to Applicants. *Id.* This inquiry is designed to preclude applicants from concealing preferred embodiments of their inventions which they have conceived. *Id.* The Examiner has failed to apply this test in rejecting the pending claims under the best mode requirement. The Examiner has failed to present evidence that Applicants concealed any embodiment of their invention which they considered to be better than the embodiments disclosed in the instant specification. Therefore, Applicants respectfully request the withdrawal of the rejection of claims 56-181 under the best mode requirement of 35 U.S.C. § 112, first paragraph.

The Examiner compares the present case to *In re Ruschig*, 379 F.2d 990, 154 U.S.P.Q. 118 (C.C.P.A. 1967). The misapplication of *Ruschig* by the Examiner cannot substitute for the two step inquiry to be applied under a proper best mode analysis. The reasoning applied in *Ruschig* is inapplicable to the best mode rejection made by the Examiner in the instant case. First, the issue in *Ruschig* was whether a claim was supported by the disclosure of the appellants' application. *Id.* 154 U.S.P.Q. at 119. The analysis in *Ruschig* by the United States Court of Customs and Patent Appeals does not address the best mode requirement. Second, the *Ruschig* analysis is inapplicable to the facts in the instant case. In *Ruschig*, a claimed specific species of a genus of chemical compounds was not named or identified by formula in the specification. *Id.* 154 U.S.P.Q. at 121. The issue was whether the disclosure of the genus along with teachings of a number of other species would lead one skilled in the art to the claimed species. The Court held that the disclosure in *Ruschig* failed to include guides directing the selections required to arrive at the claimed compound rather than any of the many other compounds that could also be made within the genus. *Id.* 154 U.S.P.Q. at 123. The Court employed the analogy of travel through a forest. The Court found that the appellants were pointing to trees, but that there were no blaze marks to single out the trees that led to the unnamed compound. *Id.* 154 U.S.P.Q. at 122. The facts in *Ruschig* are in direct contrast to the

present case. In *Ruschig* the claim limitation was *not* named or identified in the specification. In the instant case the Examiner acknowledges that Applicants' disclosure addresses the variety of claim limitations included in the claims. (Office Action at 91.) As the claim limitations are addressed by the instant specification, no blaze marks are required to lead a skilled artisan through a forest of possibilities to find them.

The Examiner asserts that he cannot recognize the pending claimed processes within the "woods." (Office Action at 92.) The PTO has previously made vague blanket rejections under 35 U.S.C. § 112, first paragraph, that assert practically every pending claim limitation is unsupported by the specification. (*E.g.*, Final Office Action of Mar. 31, 1998, pt. 8.) In response, Applicants have provided detailed support for each claim limitation. Applicants find it disingenuous for the Examiner to now assert that somehow Applicants have erred by describing numerous specific claim limitation details (*i.e.* pointing to the trees that make up the Examiner's woods.)

The Examiner asserts that there is a scattering of teachings across the multiple applications in the chain of continuity of the ancestor applications relied upon by the claim of priority in the instant application. (Office Action at 92.) The Examiner concludes that this scattering constitutes either (1) concealment of the best mode, or (2) a failure to meet the written description requirement. For the reasons set forth above in Part a), Applicants have fully complied with the written description requirement. Also as explained above in Part a), there is no scattering of teachings across applications. The instant application is a proper continuation application of Application No. 096,096, filed September 11, 1987, which in turn is a proper continuation-in-part of Application No. 317,510, filed November 3, 1981. The instant disclosure is substantially identical to the disclosure of Application No. 096,096 (the '87 disclosure.) The instant disclosure includes substantially all the subject matter in the disclosure of Application No. 317,510 (the '81 disclosure) and adds considerable details and improvements to the methods and

apparatus disclosed therein. There is no scattering of teachings across these disclosures as asserted by the Examiner.

The Examiner confusingly questions whether Applicants disclosed their best mode in relation to the terms "data," "pending claim processes as a whole," and "digital." In accordance with M.P.E.P. § 2165.03, the Examiner should assume that the best mode is disclosed unless there is evidence to the contrary. The Examiner points to no evidence indicating Applicants contemplated a best mode of carrying out the claimed invention that they have failed to disclose. That the Examiner questions whether the best mode is disclosed with respect to the "pending claim processes as a whole" is not evidence that Applicants concealed the best mode. With respect to the terms "data" and "digital," the Examiner has utterly failed to apply the first step of the proper best mode analysis. The Examiner has failed to determine that Applicants knew that one mode was better than another. Therefore, the Examiner has failed to establish a proper best mode rejection. Applicants note that this best mode rejection appears to be a repetition of the enablement rejection, which asserts that no embodiment of Applicants invention claimed using the terms "data" or "digital" is adequately disclosed. The enablement rejection is fully addressed in Part b) above.

The Examiner has failed to apply the proper analysis in rejecting claims 56-181 under the best mode requirement of 35 U.S.C. § 112. The Examiner has failed to determine whether Applicants knew that one mode was better than another at the time the application was filed. Thus, the Examiner cannot determine whether the disclosure is adequate to enable one of ordinary skill in the art to practice the best mode. As the Examiner has failed to establish a proper rejection under the best mode requirement, Applicants respectfully request that these rejections under 35 U.S.C. § 112, first paragraph, be withdrawn.

2. The Claims Comply With 35 U.S.C. § 112, second paragraph

Claims 56-181 stand rejected under 35 U.S.C. § 112, second paragraph. (Office Action at 93.) The second paragraph of 35 U.S.C. § 112 mandates that the specification conclude with claims that meet two requirements. First, the claims must set forth the subject matter that Applicants regard as their invention. Second, the claims must be definite. The legal standard for definiteness is whether a claim reasonably apprises those of skill in the art of its scope. *In re Warmerdam*, 33 F.3d 1354, 31 U.S.P.Q.2d 1754, 1759 (Fed. Cir. 1994). When rejecting any claim, the Examiner is required to state the reason for such rejection. 35 U.S.C. § 132. Section 132 is violated when a rejection is so uninformative that it prevents the applicant from recognizing and seeking to counter the grounds for rejection. *Chester v. Miller*, 906 F.2d 1574, 1578, 15 U.S.P.Q.2d 1333, 1337 (Fed. Cir. 1990). Applicants submit that the Office Action fails to demonstrate that any claim is directed to subject matter that Applicants do not regard as their invention. The Office Action also fails to demonstrate that any claim fails to reasonably apprise those of skill in the art of its scope. Applicants, therefore, respectfully request the withdrawal of these rejections under 35 U.S.C. § 112, second paragraph.

Claims 56-181 stand rejected under 35 U.S.C. § 112, second paragraph, as being indefinite. The Examiner asserts, "because Applicants' are not entitled to recapture, at a later date, that which they have left behind earlier when presenting the '87 C.I.P. disclosure, the metes and bounds of the corresponding claims too are found indefinite." (Office Action at 94.) (Parenthetical omitted) This rejection is directed to the terms "programming," "instruct," "instruction," and "information." The Examiner ambiguously references a discussion describing "the significance of incorporating by reference and lack thereof." No further reasons are given to support this rejection. The Examiner utterly fails to indicate why any claim fails to reasonably apprise those of skill in the art of its scope. This rejection is so uninformative that it prevents Applicants from recognizing and seeking to counter the grounds for rejection and is therefore invalid

under 35 U.S.C. § 132. Accordingly, Applicants respectfully request that this rejection be withdrawn. Applicants have addressed the issue of incorporation by reference in Part E.2 above. The claim language “programming” and “information” is address below in Parts c) and d) respectively. Applicants submit that any rejection purported to be asserted with respect to the claim terms “instruct” or “instruction” is so uninformative that it prevents Applicants from recognizing and seeking to counter the grounds for rejection.

At pages 96-97 of the Office Action, the Examiner also states:

Considering claims 56-181, they are replete with recitations of ‘terms whose definitions are different/diverse’, in each case the metes and bounds of the corresponding claims are found not definite. Moreover, because Applicants have failed to demonstrate support for each term, step, and process containing each term and step, what Applicants consider their invention is found not definite.

This statement fails to show that any claim does not reasonably apprise those of skill in the art of its scope. Applicants submit that this statement by the Examiner is also so uninformative that it prevents Applicants from recognizing and seeking to counter the grounds for rejection.

a) The Claims Define That Which Applicants Regard as Their Invention

Claims 56-181 stand rejected under 35 U.S.C. § 112, second paragraph, because the Examiner asserts that the claims fail to set forth the subject matter which Applicants regard as their invention. (Office Action at 93.) The Examiner argues that since Applicants successfully assert that the '81 disclosure supports the pending claims and the '81 disclosure is not duplicated verbatim in the instant specification then it follows that the claimed invention is not described in the instant specification. This logic is incorrect for the reasons given in Part 1.a)(2)(b) above, in which Applicants maintain that the subject matter in the '81 disclosure is specifically included in the instant specification.

Furthermore, the Examiner has merely pointed to evidence that Applicants believe that the claims are supported by the '81 disclosure. The conclusion that the claims fail to

set forth subject matter which Applicants regard as their invention simply does not follow from the fact that Applicants believe that the claims are supported by the '81 disclosure. Applicants believe that the claims define an invention that is fully disclosed in both the '81 disclosure and the instant specification. The Examiner has failed to point to any evidence indicating that Applicants regard the invention to be something other than what is defined by the claims. As Applicants have consistently regarded the subject matter defined by the instant claims to be their invention, Applicants respectfully request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 112, second paragraph.

b) "Use" Language Fails to Render a Claim Indefinite

In considering claims 56-181, the Examiner asserts that "use" language seems prevalent. (Office Action at 94.) Applicants respectfully assert that the claim language is proper. The Examiner fails to indicate any particular claim or claim language that he considers indefinite. Instead the Examiner suggests that Applicants provide an enumerated list detailing what steps Applicants consider active manipulation steps versus use recitations. Applicants respectfully assert that 35 U.S.C. § 112 imposes no duty on Applicants to provide such a list. To contrary, it is the Examiner's duty to examine the Application under 35 U.S.C. § 131.

Furthermore, it is unclear to what "use" language the Examiner refers. To support his assertion, the Examiner references *Ex parte Erlich*, 3 U.S.P.Q.2d 1011 (Bd. Pat. App. & Inter. 1986). The Board of Patent Appeals and Interferences in *Erlich* found that a method claim should at least recite a positive, active step. The Board did not assert that defining an apparatus in terms of its use would render a claim indefinite. The claims at issue in *Erlich* recited a use without any active, positive steps delimiting how the use was actually practiced. The Examiner does not assert that any of the pending claims recite a use *without any active, positive steps*. Thus, the Examiner's reliance on *Erlich* is

misguided. Applicants respectfully assert that any "use" language in the pending claims is proper under 35 U.S.C. § 112, second paragraph.

**c) There is no discrepancy in the use of the term
"Programming"**

In considering claims 57, 58, 61, 67, 70, 71, 72, 89, 129, and 130, the Examiner suggests that the Applicants' use of the term "programming" in the pending claims is "repugnant to the normal/usual use of said terminology." (Office Action at 95.) The Examiner further suggests that, in the '81 disclosure (in the Parent Application No. 317,510 filed November 3, 1981), the Applicants defined the term "programming" as "everything transmitted over television or radio intended for communication of entertainment or to instruct or inform". The Examiner relies on the definition of programming set forth in the abstract of the disclosure. "The purpose of the Abstract is to enable the Patent and Trademark Office and the public generally to determine quickly from a cursory inspection the nature and gist of the technical disclosure. The abstract shall not be used for interpreting the scope of the claims." 37 C.F.R. § 1.72(b). By properly making reference to the whole specification, the Examiner will get a more complete understanding of Applicants' meaning of the term "programming".

"It is the object of this invention to unlock this potential [for a significant increase in the scope and scale of multi-media and multi-channel presentations] by the development of means and methods which permit progra[m]ming to communicate with equipment that is external to television and radio receivers, particularly computers and computer peripherals such as printers." "It is the further purpose of this invention to provide means and methods to process and monitor such transmissions and presentations at individual receiver sites and to control, in certain ways, the use of transmitted progra[m]ming and the operation of certain associated equipment. Such receiver sites may be stations or systems that intend to retransmit the progra[m]ming, or they may be end users of the progra[m]ming. The present invention contemplates that certain data may

be encrypted and that certain data collected from such processing and monitoring will automatically be transfer[r]ed to a remote geographic location or locations." U.S. Patent No. 4,694,490, col. 1, ll. 22-24, 36-53.

Applicants contend that the definition of "programming", to include television and radio entertainment information, computer programming and data to control execution of a processor, in the present application is clearly supported by the definition of the term "programming" in the '81 disclosure.

Applicants assert that their use of the term "programming" in the present application is both consistent with normal/usual usage and with the parent application. *Webster's Seventh New Collegiate Dictionary* (1977) gives separate definitions for the noun and verb forms of "programming". The noun form of "programming" is defined with a series of gerunds:

"programming or programing ... n : the planning, scheduling, or performing of a program."

And the noun form of "program", which includes the word "programming" in its definition, is:

"program or programme ... n ... 1 ... : a public notice 2 a : a brief usu. printed outline of the order to be followed, of the feature or features to be presented, and the persons participating (as in a public exercise, performance, or entertainment) b : the performance of a program; esp : a performance broadcast on radio or television 3 : a plan or system under which action may be taken toward a goal 4 : CURRICULUM 5 : PROSPECTUS, SYLLABUS 6 a : a plan for the programming of a mechanism (as a computer) b : a sequence of coded instructions that can be inserted into a mechanism (as a computer) or that is part of an organism 7 : matter for programmed instruction"

The verb form of "programming" is defined with the verb form of "program" and is:

"program also programme vt -grammed or -gramed; -gramming or -graming 1 a : to arrange or furnish a program of or for : BILL b : to enter in a program 2 : to work out a sequence of operations to be

performed by (a mechanism) : provide with a program 3 : to insert a program for (a particular action) into or as if into a mechanism"

Applicants assert that these definitions are entirely consistent with Applicants' present and parent application. For example, the '81 disclosure describes a well known television program, "Wall Street Week", at U.S. Patent No. 4,694,490 (hereinafter '490) col. 19 l. 5 through col. 20 l. 7. At '490 col. 19 l. 48-53 and col. 19 l. 63 through col. 20 l. 7, Applicants disclose a sequence of operations performed by a mechanism (a computer) which includes a first output ('490 col. 19 l. 65 through col. 20 l. 2) and a second output ('490 col. 20 l. 6). This sequence of operations is performed in response to "several instruction signals" ('490 col. 19 l. 46) followed by "an instruction signal" ('490 col. 19 l. 60). (That Applicants' "signals" are coded is disclosed at '490 col. 11 lines 12-14 where a code reader passes the signals to a computer.) Applicants assert that these disclosed instruction signals ('490 col. 19 l. 48-53 and 60-67) clearly meet the dictionary definition of a program--"a sequence of coded instructions that can be inserted into a mechanism (as a computer)"--and are, in fact, what is now, and was in 1981, widely known among those of considerably less than ordinary skill in the art as "a computer program" and as "computer programming".

Applicants also assert that the first output ('490 col. 19 l. 65 through col. 20 l. 2) and a second output ('490 col. 20 l. 6), *by themselves*, also meet the dictionary definition of a program--"the performance of a program". Furthermore, Applicants contend that they constitute both computer programming *and television programming*. Being generated and outputted by a computer qualifies them as computer programming. Being displayed as an integral part of a television program--"Wall Street Week" ('490 col. 19 l. 45, 54-60, and col. 19 l. 67 through col. 20 l. 2)--qualifies them as television programming.

Finally, Applicants assert that this disclosure is in no way inconsistent with the meaning given to "programing" in the Abstract of Applicants' parent disclosure--

"everything transmitted over television or radio intended for communication of entertainment or to instruct or inform." Applicants clearly disclose that the signals are "instruction signals embedded in the 'Wall Street Week' programing transmission" ('490 col. 19 l. 43-44) and that "These signals instruct" ('490 col. 19 l. 48) and "This signal instructs" ('490 col. 19 l. 64-65).

For the reasons set forth above, Applicants assert that the term "programming" as used throughout the instant application to include what are commonly known as television, radio and computer programming is clearly and unambiguously supported by the specification as filed and withdrawal of the corresponding rejection is respectfully requested.

d) There is no discrepancy in the use of the term "Information"

In considering claims 63, 65, 74, 75, 78, 84, 91, 93, 96, 98, 107, 108, 110, 113, 114, 116, 118, 119, 123, 131, 142, 146, 155, 162, 167, 170, 171, 174, 176, 178, and 179, the Examiner notes that these claims include the term "information." (Office Action at 96.) The Examiner asserts, "The metes and bounds of the claims are not definite because: the '81 and '87 C.I.P. disclosures define the terms differently so that it is not clear whether the old definition is present now or whether it was 'left behind'." (Office Action at 96.) The Examiner has utterly failed to provide any reasons for concluding that the claims including the term "information" would not reasonably apprise those of skill in the art of the claim scope. The Examiner implies that there is a conflict in the use of the term "information" in the '81 disclosure and the use of the same term in the instant specification. Applicants respectfully assert that there is no such conflict in the use of the term "information." The Examiner fails to identify any conflict whatsoever. The Examiner's implication of a conflict is so uninformative that it prevents Applicants from recognizing and seeking to counter any grounds for rejection that the Examiner may be intending to assert. Applicants respectfully assert that the use of the term "information"

in the present claims fully complies with the requirements of 35 U.S.C. § 112, second paragraph.

e) **There is no discrepancy in the use of the terms
"Conjunction," "Combine," and "Combined"**

In considering claims 56, 75, 80, 84, 116, 124, 152, 157, 162, 171, and 175, the Examiner notes that these claims include the term "conjunction." (Office Action at 97.) The Examiner asserts, "[conjunction] is understood to have been first introduced in the '87 C.I.P., as Applicants allege support to the '81 disclosure, what Applicants consider their invention is found not definite." (Office Action at 97.) The Examiner's conclusion fails to state a ground for rejection under 35 U.S.C. § 112, second paragraph. Furthermore, the Examiner gives no reasons to support his conclusion. The Examiner merely asserts that the term "conjunction" was not used in the '81 disclosure. This fact does not render the use of the term "conjunction" indefinite. There is no reason a term must be used in a parent disclosure for it to be definite when used in the claims of a subsequent application. Applicants assert that for at least these reasons, the Examiner has failed to assert a proper rejection against the claims including the term "conjunction."

The Examiner also notes that the terms "combine" and "combined" were not introduced until the '87 C.I.P. Applicants assert for at the reasons discussed above with respect to the term "conjunction" that this fact does not render the terms "combine" or "combined" indefinite. Applicants respectfully assert that the pending claims including the terms "combine" and "combined" reasonably apprise those of skill in the art of their scope.

H. Response to Rejections under 35 U.S.C. § 102

1. Rejection under 102 (b) over Applicants' U.S. Pat. Nos. '490 & '725

Claims 56-181 stand rejected under 35 U.S.C. § 102(b). The Examiner asserts that claims 56-181 are clearly anticipated by Applicants' own U.S. Patent Nos. 4,694,490 and 4,704,725. (Office Action at 100.) The instant application claims the benefit under 35 U.S.C. § 120 of the filing date of both the previous applications that matured into the patents relied upon by the Examiner. Accordingly, neither of the patents relied upon by the Examiner is available as a reference under 35 U.S.C. § 102(b). The Examiner asserts that the instant specification fails to adequately support the instant claims. This assertion is incorrect and irrelevant to Applicants' claim of priority under 35 U.S.C. § 120.

Under 35 U.S.C. § 120, an application obtains the benefit of the filing date of a previously filed patent application if (a) the invention is disclosed in the manner provided by the first paragraph of section 112 in the previously filed application, (b) the application is filed by inventors named in the previously filed application, (c) the application is filed before the patenting or abandonment of or termination of proceedings on an application similarly entitled to the benefit of the filing date of the first application, and (d) the application contains a specific reference to the earlier filed application. The instant application meets each of these requirements with respect to Applicants' previous Application No. 317,510 filed November 3, 1981. The Examiner acknowledges that Application No. 317,510, discloses the subject matter of the instant claims. The same inventors as filed the instant application filed application No. 317,510. The instant application was filed before the termination of proceedings of Application No. 113,329, filed August 30, 1993, (currently pending) which is similarly entitled to the benefit of the filing date of Application No. 317,510. The instant application contains a specific reference to the entire chain of Applicants' applications extending back to Application No. 317,510. As the instant application meets all the requirements of 35 U.S.C. § 120,

This Page Blank (uspto)

the instant application is entitled the benefit of the effective filing date of November 3, 1981. Accordingly, neither U.S. Patent No. 4,694,490 nor No. 4,704,725 are available as prior art under 35 U.S.C. § 102(b) as neither was patented or published more than one year prior to November 3, 1981.

Furthermore, the Examiner asserts, "this rejection, under 35 U.S.C. § 102(b), is caused by Applicants choice to cite passages that did not exist in the original '87 C.I.P. disclosure." Applicants respectfully assert that the showing that the instant claims are supported by the '81 disclosure cannot form the basis for this rejection under 35 U.S.C. § 102(b). To the contrary, the showing establishes that the instant claims are entitled to an effective filing date of November 3, 1981. Additionally, Applicants assert that the instant claims are fully supported by the instant specification as discussed above in Part G.1.a) above.

For at least the above reasons, Applicants respectfully submit that U.S. Patents Nos. 4,694,490 and 4,704,725 are not available as prior art with respect to the presently pending claims. Applicants, therefore, request the withdrawal of the rejection of claims 56-181 under 35 U.S.C. § 102(b) as being anticipated by U.S. Patents 4,694,490 and 4,704,725.

2. Rejection under 102 (a, b & e) over Campbell et al., U.S. Pat. No. '791.

Claims 56-182 stand rejected under 35 U.S.C. § 102 (b) as being anticipated by the Campbell et al., U.S. Pat. No. 4,536,791.

a) Summary of Office Action's Rejection Over Campbell et al.

The following section attempts to summarize and respond to the January 7th Office Action rejection over Campbell et al. since the Office Action fails to precisely specify Applicants' claim language in its analysis.

Applicants have listed 22 items of the Office Action's language comprising charts and paragraphs wherein the Office Action equates statements allegedly representing Applicants' claim language to the disclosure of Campbell et al. for the purposes of the rejection.

1. The Office Action states that Campbell et al. teaches:

Statements allegedly representing Applicants' instant claim language.	Disclosure of Campbell et al.
Communicating information at a multimedia receiver station;	(addressable converter, item 40 Figure 1)
the receiver station containing one or more receivers;	(addressable converter) (item 40, per Campbell et al. teaching, in Figure 6 wherein item 100 receives multimedia signaling)
a computer connected to the receiver for processing and communication information;	(Campbell et al. Figure 7 shows dissection of Figure 6 item 104 in which computer 410 of Figure 7 receives video and graphics from Figure 6 item 100)
a plurality of output devices;	(Figure 7 shows the process of channeling information to graphics output circuitry and also to video output circuitry)
inputting a subscribers command;	(Figure 12 item 334 inputs key word) When subscribers desire to watch special events, higher tiers, or any unauthorized programming.
controlling the receiver station to receive a signal in response to the key word entry the signal comprising a signal which permits operation of the receiver station in a designated media operation;	(Fig 11 item 200) (subscriber command) (same or different??- either Fig 11 item 200 or Fig 11 item 206 depending on whether a signal is meant to be same or different than previous recitation) (Campbell et al. teach that the threshold code be entered by the user, col 14 line 18, which effects signal 200 to comprise a corresponding 206 permitting operation or the receiver station to allow previously ineligible programming)
detecting the presence of two or more instruct-to-coordinate signals at the receiver station;	(a first signal is taught by Campbell et al. is channel control word signal 200 of Figure 11, the second signal is the event enable word signal 220)
each instruct-to-coordinate signal designating: channel control word designates (1)-a portion of multimedia programming signal to receive by designating tier code and event enable word signal 200 designates (2)- a portion of a multimedia programming signal to communicate to a memory location;	 (Figure 11, item 200 with item 202) Wherein items 222, 224, 226, 228 are stored in item 104 (see col 13 line 61 thru. col 14 line 8)
Communicating one or more units of multimedia programming in response to the two-or more instruct-to-coordinate signals.	(Campbell et al. teach that after special event codes are stored in item 104 in response to entry of keyword an activation of channel number 226, that the special

program be output to the requesting subscriber)

Applicants traverse the above rejection comparing Applicants' alleged claims to the teaching of Campbell et al. primarily on the basis that the Office Action fails to reject Applicants' claims. The Office Action fails to apply Applicants' claim language to Campbell et al. and uses the following language that fails to correspond to Applicants' instant claim language:

communicating information at a multimedia receiver station;

a plurality of output devices¹;

inputting a subscriber command²;

controlling the receiver station to receive a signal in response to the [subscriber command];

detecting the presence of two or more instruct-to coordinate signals at the receiver station;

each instruct-to-coordinate signal designating...(1) a portion of multimedia programming signal to receive...; and (2) a portion of a multimedia programming signal to communicate to a memory location; and

communicating one or more units of multimedia programming in response to the two-or more instruct-to-coordinate signals.

2. The Office Action states that Campbell et al. does specifically teach that television programming displays that [sic] promotes a multi-media product or service.

¹ The only instance recited in Applicants' claim language of a plurality of output devices is in claim 145, "further comprising the step of controlling...a second output device based on said control signal," and not in any independent claim.

² The only instance recited in Applicants' claim language of relating to a subscriber is "user input to process" or "processing user input" in claims 99, 104, 144, 149 & 152.

The Office Action again fails to apply Applicants' claim language to Campbell et al. since the above language fails to correspond to Applicants' instant claim language. Nowhere in the instant application do Applicants use the claim language "television programming that promotes a multi-media product or service".

3. The Office Action states that Campbell et al. teach promoting special events available on non-authorized channels so that subscribers would become aware of any event of interest and then order that event, i.e. advertise.

Again, the Office Action again fails to apply Applicants' claim language to Campbell et al. since the above language fails to correspond to Applicants' instant claim language. Nowhere in the instant application do Applicants use the claim language "promoting special events available on non-authorized channels so that subscribers would become aware of any event of interest and then order that event".

4. The Office Action states that Campbell et al. further teach the receiving station being programmed to allow viewing of some channels but not others.

Again, the Office Action again fails to apply Applicants' claim language to Campbell et al. since the above language fails to correspond to Applicants' instant claim language. Nowhere in the instant application do Applicants use the claim language that the receiver station is programmed "to allow viewing of some channels but not others".

5. The Office Action states that Campbell et al. teach processing received programming based on a predetermined fashion by comparing a requested channel to an authorized channel and then making a decision whether to switch to graphics display and key word entry prompt or to allow viewing of the selected program and channeling video signal to video descrambler.

Again, the Office Action again fails to apply Applicants' claim language to Campbell et al. since the above language fails to correspond to Applicants' instant claim language. Nowhere in the instant application do Applicants use the claim language "processing received programming based on a predetermined fashion by comparing a requested channel to an authorized channel and then making a decision whether to switch to graphics display and key word entry prompt or to allow viewing of the selected program and channeling video signal to video descrambler".

6. The Office Action states that Campbell et al. teach processing subscriber command based on said one or more instruct-to-coordinate signals.

As mentioned in footnote 1 of the above point 1, Applicants claim "user input to process" and "processing user input" in claims 99, 104, 144, 149 & 152.

With respect to dependent claims 99 & 149, Applicants' claim language states; "designates a specific user input to process, said method further comprising the step of generating output by processing said specific user input." There is no language in the claim that the processing of Applicants' specific user input be based on anything, let alone "based on said one or more instruct-to-coordinate signals."

With respect to dependent claim 104, 144 & 152, Applicants' claim language states, respectively:

"the step of processing user input based on said receiver specific control signal,"

"processing user input based on said generated control signal," and

"wherein said one or more control signals are operative at said at least one receiver station to...designate a user input to be processed based on said downloadable processor instructions."

Again, the Office Action fails in the instant analysis since there is no language in the claim that processing Applicants' user input is "based on said one or more instruct-to-coordinate signals."

7. The Office Action states that Campbell et al. teach processing viewer's reaction based on one of said one or more instruct-to-coordinate and outputting some programming to a second output device based on inputting and processing.

Again, as in the above response to points 1 & 6, the Office Action again fails to apply Applicants' claim language to Campbell et al. since the above language fails to correspond to Applicants' instant claim language. Nowhere in the instant application do Applicants use the claim language "processing viewer's reaction based on one of said one or more instruct-to-coordinate and outputting some programming to a second output device based on inputting and processing."

8. The Office Action states that Campbell et al. teach processing the subscriber command, and communicating information based on the step of entering the [subscriber command] to the remote station based on inputting and processing.

As mentioned above in points 1, 6 & 7, with respect to Applicants' claimed processing of a subscriber input, claims 99, 104, 144, 149 & 152 fail to include any language of "communicating information based on the step of entering the [subscriber command] to the remote station based on inputting and processing."

9. The Office Action states that Campbell et al. teach:

Statements allegedly representing Applicants' instant claim language.	Disclosure of Campbell et al.
two-way-cable communication specifically from subscriber to remote data collection stations which include:	
inputting viewers reaction at a subscriber station;	(prompt for key word entry item 334 Figure 12)
receiving at a subscriber station information that designates an instruct signal to process/output to deliver in consequence of specific subscriber input;	(specific subscriber inputs of eligibility threshold setting or keyword entry allows deliverance of a previously in-eligible program to be outputted to the subscriber)
determining the presence of specific subscriber reaction input at the subscriber station by processing sand viewers or participants;	(matching entered key word to predetermined key word by processing entered keyword)
processing an instruct signal	(word 230 Figure 11)

effective to coordinate multimedia programming presentation based on the subscriber input at the subscriber station in consequence to the step of determining;	(key word or newly entered eligibility threshold)
transferring from the subscriber station to one or more remote data collection stations an indicia confirming delivery of the instruct signal from the step of processing or conforming delivery of the same from the step of processing.	(word 230 Figure 11) (the system monitors viewed programs, col 3 line 24 for purposes which include billing, statistic gathering, etc

Applicants traverse the above rejection comparing Applicants' alleged claims to the teaching of Campbell et al. primarily on the basis that the Office Action fails to reject Applicants' claims. The Office Action fails to apply Applicants' claim language to Campbell et al. and uses the following language that fails to correspond to Applicants' instant claim language:

two-way-cable communication specifically from subscriber to remote data collection stations³;

inputting viewers reaction at a subscriber station⁴;

receiving at a subscriber station information that designates an instruct signal to process/output to deliver in consequence of specific subscriber input;

determining the presence of specific subscriber reaction input at the subscriber station by processing and viewers or participants;

processing an instruct signal effective to coordinate multimedia programming presentation based on the subscriber input at the subscriber station in consequence to the step of determining; and

³ Applicants claim "communicating...to a remote data source," and "receiving from said remote data source said data to serve as a basis for displaying said video presentation," in claim 56, and similarly in claim 58, 59, 63, & 109.

⁴ See footnote 2, where the only instance recited in Applicants' claim language of relating to a subscriber is "user input to process" or "processing user input" in claims 99, 104, 144, 149 & 152.

transferring from the subscriber station to one or more remote data collection stations an indicia confirming delivery of the instruct signal from the step of processing or conforming delivery of the same from the step of processing.

10. The Office Action states that Campbell et al. teach:

Statements allegedly representing Applicants' instant claim language.	Disclosure of Campbell et al.
storing subscriber instruction to receive one or [more] specific mass medium programs, data, news items, or computer control instructions;	(the hub end stores tier code item 202 Figure 11, eligibility threshold code item 238 Figure 11, etc... based on subscriber authorization)
and receiving one or more specific mass medium programs, data, news items, or computer contorts instruction in accordance with the instructions.	(column 16 lines 47-59 show teachings wherein programs available based on tier code item 202 Figure 11, eligibility threshold code item 238 Figure 11, etc ...)

Applicants traverse the above rejection comparing Applicants' alleged claims to the teaching of Campbell et al. primarily on the basis that the Office Action fails to reject Applicants' claims. The Office Action fails to apply Applicants' claim language to Campbell et al. and uses the following language that fails to correspond to Applicants' instant claim language (specifically the underlined portions):

storing subscriber instruction to receive one or [more] specific mass medium programs, data, news items, or computer control instructions; and
receiving one or more specific mass medium programs, data, news items, or computer [control] instruction in accordance with the instructions.

11. The Office Action states that Campbell et al. teach:

Statements allegedly representing Applicants' instant claim language.	Disclosure of Campbell et al.
instruction signal input by the subscriber storing subscriber instruction to process or present one or more mass medium programs;	(eligibility threshold codes) (col 14 line 18) (event enable word is stored in item 104 see col 13 lines 61 thru col 14 line 8)
processing or presenting one or more specific mass medium programs with the instruction.	(when the special event is broadcast then the special event is made available via video descrambling circuitry -Figure 7 item 101)

Applicants traverse the above rejection comparing Applicants' alleged claims to the teaching of Campbell et al. primarily on the basis that the Office Action fails to reject Applicants' claims. The Office Action fails to apply Applicants' claim language to Campbell et al. and uses the following language that fails to correspond to Applicants' instant claim language:

instruction signal input by the subscriber storing subscriber instruction to process or present one or more mass medium programs; and

processing or presenting one or more specific mass medium programs with the instruction.

12. The Office Action states that Campbell et al. teach that the information [which] designates a specific subscriber input or said instruct signal (eligibility threshold code) is detected in an information transmission from a data or programming source.

Again, the Office Action again fails to apply Applicants' claim language to Campbell et al. since the above language fails to correspond to Applicants' instant claim language. Nowhere in the instant application do Applicants use the claim language information which designates a specific subscriber input or said instruct signal is detected in an information transmission from a data or programming source.

13. The Office Action states that the processor taught by Campbell et al. is inherently programmed to respond to data from the programming source hub end transmitter.

Applicants claim language recites "plurality of receiver stations...each of which is...programmed to process," in claim 75, 110, 152 & 171, "plurality of receiver stations is...programmed to respond," in claim 131, "at least one receiver station is programmed to process," in claim 162.

14. The Office Action states that the detector 100 of Figure 6 does detect programming and control signaling wherein both data and control signaling and instruct signaling are passed to item 104 of Figure 6.

Applicants claim language recites detecting signals including discrete signals, receiver stations adapted to detect signals, and signal detectors.

15. The Office Action states that Campbell et al. teach:

controlling the remote intermediate data transmitter station to communicate data to one or more receiver stations, with the remote transmitter station including a broadcast or cablecast transmitter for transmitting one or more signals which are effective at a receiver station to instruct a computer or processor;	(Campbell et al. abstract and Figure 7 processor 410; particularly not that the user of the receiving station enters an eligibility threshold code col 14 line 18 which is effective to allow viewing of pre-authorized programming and hence instruct processor 104 of Figure 6 to control the programming reception)
a plurality of selective transmission devices;	(video device circuitry Figure 7 item 101 or graphics device circuitry Figure 7 item 124)
a data receiver;	(Figure 6)
control signal detector;	(item 104 or internal circuitry of item 104 depicted in Figure 7)
controller or computer for detecting the control signaling for controlling program output based on the eligibility code 206; receiving instruct signaling item 238 must be received by the transmitter station in order to be transmitted back to the receiver station as illustrated by Figure 11;	(item 410 of Figure 7) (depicted in Figure 11) (see discussion of eligibility code threshold authorization in col 14 line 18)
for control signals are inherently used to communicate the eligibility threshold code.	

Applicants traverse the above rejection comparing Applicants' alleged claims to the teaching of Campbell et al. primarily on the basis that the Office Action fails to reject Applicants' claims. The Office Action fails to apply Applicants' claim language to Campbell et al. and uses the following language that fails to correspond to Applicants' instant claim language:

controlling the remote intermediate data transmitter station to communicate data to one or more receiver stations, with the remote transmitter station including a broadcast or cablecast transmitter for transmitting one or more signals which are effective at a receiver station to instruct a computer or processor;

a plurality of selective transmission devices⁵;
a data receiver;
control signal detector;
controller or computer for detecting the control signaling for controlling program output based on [a signal];
receiving instruct signaling...by the transmitter station in order to be transmitted back to the receiver station;
[wherein] control signals are inherently used to communicate the...code.

16. The Office Action states that Campbell et al. teach 'a specific time', wherein a specific time is merely considered the time the control signals are transmitted.

Applicants claim, "transmitting said at least one control signal from said origination transmitter before a specific time," in claim 80;

"at least one of said video and said instruct signal to a second transmitter at said specific time," in claim 81;

"specific time is a scheduled time of transmitting," in claim 83 & 119;

"transferring said at least one control signal to said at least one origination transmitter before a specific time," in claim 116; and,

"transmitting said one or more control signals from said origination transmitter before a specific time," in claim 157.

17. The Office Action states that Campbell et al. teach embedding specific one of said one or more control signals within the information transmission between the transmitter station and the receiver station.

⁵ Claims 92 & 161, recite "one of a plurality of selective transfer devices."

“embedding a specific one of said at least one control signal in a non-visible portion of a signal containing said video before transmitting said video to said remote intermediate transmitter station,” in claims 82 & 159; and,

“embedding said at least one control signal in an information transmission containing said first discrete signal before transmitting said first discrete signal to said remote intermediate transmitter station”, in claim 118.

18. The Office Action states that Campbell et al. teach:

Statements allegedly representing Applicants' instant claim language.	Disclosure of Campbell et al.
Communication between a transmitter station and a receiver station;	(abstract)
including delivery of media to the receiver station from the transmitter station via a transmitter;	(it is inherent to the process of receiving programs at the receiver station for the programs to be delivered to a transmitter for transmitting to that receiver station)
the transmitter station receives signaling of a eligibility threshold code from the receiver station;	(col 14 line 18; note Figure 11 shows signaling in the direction of the transmitter station to receiver station including item 238 necessitating that the eligibility threshold was first communicated in the direction of the receiver station to the transmitter station after authorization of a certain eligibility threshold code is given prior to subsequent Figure 11 depiction of the threshold being transmitted back to the receiver station as item 238)
the eligibility threshold code or the eligibility code item 206 or item 200 channel control word operates at the receiver station to coordinate which programs will be viewed upon request based on tier etc ;	(considered instruct signaling)

Applicants traverse the above rejection comparing Applicants' alleged claims to the teaching of Campbell et al. primarily on the basis that the Office Action fails to reject Applicants' claims. The Office Action fails to apply Applicants' claim language to Campbell et al. and uses the following language that fails to correspond to Applicants' instant claim language:

the transmitter station receives signaling of a eligibility threshold code from the receiver station; and

the eligibility threshold code or the eligibility code or channel control word operates at the receiver station to coordinate which programs will be viewed upon request based on tier [request].

19. The Office Action states that Campbell et al, per discussion above, do communicate at least one signal of eligibility threshold code in order for it to be transmitted back as item 238 personal schedule; moreover, they teach embedding one or more control signals in the unit of programming before transmitting the unit to the remote transmitter stations is inherent to Campbell et al. teachings⁶.

Again, the Office Action again fails to apply Applicants' claim language to Campbell et al. since the above language fails to correspond to Applicants' instant claim language. Nowhere in the instant application do Applicants use the claim language communicate at least one signal of eligibility threshold code in order for it to be transmitted back.

20. The Office Action states that Campbell et al. teach that the unit of programming comprises audio or text, or video. The unit of programming is taught to be a television program by Campbell et al.

Applicants claims recites "downloadable code programs said processor to output at least one of video, audio, and text one of simultaneously and sequentially with said video presentation," in claim 78,

"to output at least two of video, audio, and text at least one of simultaneously and sequentially with said portion of said video presentation," in claim 113; and,

"said downloadable processor instructions program said processor to output video, audio, or text simultaneously or sequentially with said video image," in claim 154.

⁶ See response to point 17 above.

21. The Office Action states that Campbell et al. teach the claimed subject matter including the display of stock market quotations, news [stories], stock quotations etc. Applicants fail to understand how this characterization of Campbell et al. is relevant to Applicants' instant claims since there is no recitation anywhere of stock market quotations, news stories, stock quotations.

22. The Office Action states in consideration of priority, it is noted that the term 'combined' is found to have been first introduced when the '87 C.I.P. disclosure was filed. Also, claims 56, 75, 80, 84, 116, 124, 152, 157, 162, 171, 175, are found to recite the term 'conjunction'. However, the term 'conjunction' is found to have been first introduced when the '87 C.I.P. disclosure was filed.

Applicants fail to understand how the above statement relates to the prior art rejection over Campbell et al. and here by traverses its use in the prior art rejection over Campbell et al. as having no relevance to the teaching of Campbell et al.

b) Characterization of Campbell et al.

The following section broadly summarizes the teaching of Campbell et al. to distinguish Applicants' claim recitations in the following sections.

Campbell et al. relates to addressable cable television control systems with a video formatted data transmission. Campbell et al. discloses an addressable cable television control system that transmits a television program and data signal transmission from a central station to a plurality of remote user stations. Campbell et al.'s data signals include both control and text signals in video line format that are inserted on the vertical interval of the television signals. An intelligent converter at each remote user location processes the data signals to enable controlled descrambling of the television transmission to the system on the basis of channel, tier of service, special event and

program subject matter. The converter includes apparatus for interfacing with a two-way interactive data acquisition and control system.

Campbell et al. teaches a head end station that includes a central data system utilizing a control computer that gathers data from a wide variety of sources and formats the data for transmission on video frequency channels. The formatted data is then transmitted by communication link to a television program processor where it is incorporated into the vertical blanking intervals of video signals by a variety of television program sources. The head end unit then transmits the combined cable television and data signal to remote subscribers. Normally, the signals are then transmitted through a cable network to a plurality of subscribers. The signals are received by an addressable converter that determines whether to descramble the received television signal based on proper subscriber, event and eligibility data stored at the receiver station, or to leave the signal in its scrambled format.

c) Applicants' Claim 56

With respect to Applicants' amended claim 56, Campbell et al. fails to teach, *inter alia*:

communicating one of said at least said first request and a second request to a remote data source;

receiving from said remote data source said data to serve as a basis for displaying said video presentation;

processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and

displaying said locally generated image at said video output device in conjunction with said image from said remote video source.

Campbell et al. teaches the receiver converter 40 can display a locally generated image. The first instance is where the user requests a new channel of programming:

Referring now to FIG. 12, a flow diagram is shown describing the operation of a converter 40 in selecting a given channel and determining access to a given program. Reference should also be made to FIG. 5 for the converter components. The process begins at step 310 with the user entering a new channel number on the converter keyboard. At that point, the converter control logic implements several preparatory steps in the converter. The appropriate video switches in text/graphics generator 118 switch to a text display mode which in turn provides a black screen output to the television set. Converter control logic 104 also signals the audio level/mute control 120 to mute the sound output to the television set. Tuner 106 retunes to the requested channel and vertical interval data extractor 114 separates out the data transmitted on the vertical interval of the selected television signal. (Column 14 line 67 to column 15 line 15.)

The converter control logic unit 104 then makes several comparisons to between the subscriber addressing data and the channel control word in the programming on the selected channel. See, column 15 lines 16-39. If the control logic unit 104 determines that the user station is not enable to receive the programming on the requested channel,

step 326 is taken in which the text/graphics generator 118 generates an appropriate [sic] message for display on the television screen of the user indicating that the user station is not authorized for reception of the program currently being broadcast on a selected channel. The converter control logic then cycles back to step 310 where it waits for the user to enter a new channel number. (Column 15 lines 43-50.)

In this instance, even though the requested channel is actually tuned to and programming is being received for comparison purposes, the programming on the requested channel is not output for display.

If proper authorization is confirmed at converter 40, then the converter 40 is enabled to process the television signal received on the requested channel wherein,

the video descrambler 116 is enabled to process the video signal of the selected television program and the audio level/mute control unit 120 is enabled to transmit the audio signal to the television set. (Column 15 lines 62-65.)

Another instance of a locally generated item for display at the receiver station is when the eligibility code threshold is exceeded. When this happens, the converter control logic 104 of converter 40,

takes the next step 334 which is to enable text/graphics generator 118 to generate an appropriate message for display on the television set of the user. The message instructs the user to enter his confidential [sic] key number on the converter keyboard 139 in order to enable viewing of the program in question. The entered number is then compared with the subscriber's key number as given in key number code 236 of the eligibility word 230 as indicated at decision step 338. If the key number matches with the entered number, the converter control logic 104 proceeds to the enabling step 332 as previously mentioned. If the entered number does not match with the subscriber's key number, the converter control proceeds to step 326 in which the user is informed that he is not authorized for reception of the program in question. (Column 15 line 67 to column 16 line 14.)

At no time in this additional example in Campbell et al. is the requested programming ever displayed with the locally generated instructional message. The message from text/graphics generator 118 is for displaying in the similar manner to column 15 lines 5-12 where the display screen is blackened and the audio is muted, thus teaching that no remotely generated programming is output for display from converter 40 when generator 118 is activated.

Finally, Campbell et al. teaches that the

text/graphics generator 118 includes a plurality of video switches which are used to bypass the text/graphics generator with the channel video. Optionally the video switches also permit the channel number display to be superimposed on the video signal of the channel which is being presented. (Column 9 lines 34-39.)

However, Campbell et al. fails to teach receiving from said remote data source said data to serve as a basis for displaying said video presentation, wherein the video presentation comprises a locally generated image with said image from said remote video source.

Applicants respectfully submit that the cited art does not anticipate claim 56 since Campbell et al. fails to disclose every element of the claimed invention, and Applicants respectfully request that the 35 U.S.C. § 102 rejection of claim 56 be withdrawn.

Claims 57-74 & 89-91 depends upon independent claim 56. As discussed *supra*, Campbell et al. fails to disclose every element of claim 56 and thus, *ipso facto*, Campbell

et al. fails to anticipate dependent claims 57-74 & 89-91, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

d) Applicants' Claim 75

With respect to Applicants' amended claim 75, Campbell et al. fails to teach, *inter alia*:

a method of delivering a video presentation...said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image;

receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;

receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation.

There is no teaching in Campbell et al. where a second image contains at least one datum that at least one of completes and supplements said first video image. The prompting screens generated by generator 118 and the channel numbers fail to contain a datum that either completes or supplements a first video image. Additionally, there is no teaching in Campbell et al. of a downloadable processor instruction capable of causing said at least one receiver station to generate locally and output said second video image.

See above references and citations to Campbell et al. And finally, there is no teaching of a control signal that cause the execution of a downloadable processor instruction and to deliver the second video image.

Claims 76-79 depends upon independent claim 75. As discussed *supra*, Campbell et al. fails to disclose every element of claim 75 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 76-79, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

e) Applicants' Claim 80

With respect to Applicants' amended claim 80, Campbell et al. fails to teach, *inter alia*, an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video. There is no teaching in Campbell et al. of any transmitted signal that causes the converter 40 to display of a locally generated portion of a video presentation in conjunction with said transmitted video presentation.

Claims 81-83 & 92 depends upon independent claim 80. As discussed *supra*, Campbell et al. fails to disclose every element of claim 80 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 81-83 & 92, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

f) Applicants' Claim 84

With respect to Applicants' amended claim 84, Campbell et al. fails to teach, *inter alia*,:

wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction; and

wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited processor instruction and the functionality of the discrete signals.

Claims 85-88 depends upon independent claim 84. As discussed *supra*, Campbell et al. fails to disclose every element of claim 84 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 85-88, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

g) Applicants' Claim 93

With respect to Applicants' amended claim 93, Campbell et al. fails to teach, *inter alia*,

organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;

passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;

responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;

generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and

outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information into processor instructions which cause the generation of an image to be output to replace said only said portion of said video image.

Claims 94-109 depends upon independent claim 93. As discussed *supra*, Campbell et al. fails to disclose every element of claim 93 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 94-109, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

h) Applicants' Claim 110

With respect to Applicants' claim 110, Campbell et al. fails to teach, *inter alia*, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data; and

receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of

receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited processor instruction comprised of information organized from said information contained in said first discrete signal and information contained in a second discrete signal, and a control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction.

Claims 111-115 depends upon independent claim 110. As discussed *supra*, Campbell et al. fails to disclose every element of claim 110 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 111-115, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

i) Applicants' Claim 116

With respect to Applicants' amended claim 116, Campbell et al. fails to teach, *inter alia*,

wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction;

receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information

contained said first discrete signal with said information contained in said second discrete signal.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited displaying a locally generated image in conjunction with said video in response to at least one processor instruction, and the processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal. Additionally, there is no reference to organizing said information contained said first discrete signal with said information contained in said second discrete signal

Claims 117-122 depends upon independent claim 116. As discussed *supra*, Campbell et al. fails to disclose every element of claim 116 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 117-122, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

j) Applicants' Claim 123

With respect to Applicants' amended claim 123, Campbell et al. fails to teach, *inter alia*:

wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device;

receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;

said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of

receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited code and identifier, instruct signal to generate locally and output said second image of said video presentation for delivery in conjunction with said first image, and the first discrete signal including only partial information of said one of a code and an identifier.

Claims 124-141 depends upon independent claim 123. As discussed *supra*, Campbell et al. fails to disclose every element of claim 123 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 124-141, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

k) Applicants' Claim 142

With respect to Applicants' amended claim 142, Campbell et al. fails to teach, *inter alia*,

organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;

passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;

generating only a portion of said video image based on said step of responding to said at least one processor instruction; and

outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information into a processor instruction and generating and outputting only a portion of said video image with respect to the processor instruction.

Applicants respectfully submit that the cited art does not anticipate claim 142 since Campbell et al. fails to disclose every element of the claimed invention, and Applicants respectfully request that the 35 U.S.C. § 102 rejection of claim 142 be withdrawn.

l) Applicants' Claim 143

With respect to Applicants' amended claim 143, Campbell et al. fails to teach, *inter alia*,

organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;
generating a signal based on said processor instructions; and
outputting at least a portion of said video presentation based on said generated signal.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information in a first and second discrete signal into processor instructions and generating and outputting a portion of said video presentation based on said generated signal.

Claims 144-151 depends upon independent claim 143. As discussed *supra*, Campbell et al. fails to disclose every element of claim 143 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 144-151, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

m) Applicants' Claim 152

With respect to Applicants' amended claim 152, Campbell et al. fails to teach, *inter alia*, receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited control signal operative at the receiver station to direct said video image to said output device, designate a processor ... or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image.

Claims 153-156 depends upon independent claim 152. As discussed *supra*, Campbell et al. fails to disclose every element of claim 152 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 153-156 and therefore, this rejection should be withdrawn and the claims be permitted to issue.

n) Applicants' Claim 157

With respect to Applicants' amended claim 157, Campbell et al. fails to teach, *inter alia*, an instruct signal which is effective at said at least one receiver station to

generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited instruct signal effective to generate and output a local image in conjunction with said video image.

Claims 158-161 depend upon independent claim 157. As discussed *supra*, Campbell et al. fails to disclose every element of claim 157 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 15-161, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

o) Applicants' Claim 162

With respect to Applicants' amended claim 162, Campbell et al. fails to teach, *inter alia*, said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited said first of said plurality of discrete signals which enable the processing of code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals.

Claims 163-166 depend upon independent claim 162. As discussed *supra*, Campbell et al. fails to disclose every element of claim 162 and thus, *ipso facto*,

Campbell et al. fails to anticipate dependent claims 163-166, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

p) Applicants' Claim 167

With respect to Applicants' claim 167, Campbell et al. fails to teach, *inter alia*, organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited step of organizing information into a processor instruction and the step of displaying a second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen.

Claims 168-170 depend upon independent claim 167. As discussed *supra*, Campbell et al. fails to disclose every element of claim 167 and thus, *ipso facto*,

Campbell et al. fails to anticipate dependent claims 168-170, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

q) Applicants' Claim 171

With respect to Applicants' amended claim 171, Campbell et al. fails to teach, *inter alia*,

at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image;

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station; and

wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited second completed full-screen video graphic image, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen, and receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction.

Claims 172-174 depends upon independent claim 171. As discussed *supra*, Campbell et al. fails to disclose every element of claim 171 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 172-174, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

r) Applicants' Claim 175

With respect to Applicants' claim 175, Campbell et al. fails to teach, *inter alia*, at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image; and

one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image,

Claim 176 depends upon independent claim 175. As discussed *supra*, Campbell et al. fails to disclose every element of claim 175 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claim 176, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

s) Applicants' Claim 177

With respect to Applicants' claim 177, Campbell et al. fails to teach, *inter alia*, one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen.

Claim 178 depends upon independent claim 177. As discussed *supra*, Campbell et al. fails to disclose every element of claim 177 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claim 177, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

t) Applicants' Claim 179

With respect to Applicants' claim 179, Campbell et al. fails to teach, *inter alia*,:
organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal, and passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed

full-screen video graphic image, and displaying said second completed full-screen video graphic image at said video monitor.

Claims 180-182 depends upon independent claim 179. As discussed *supra*, Campbell et al. fails to disclose every element of claim 179 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 180-182, and therefore, this rejection should be withdrawn and the claims be permitted to issue.

u) Summary

Applicants further respectfully submit that claims 56-182 in the present application should be allowed because these methods are not disclosed, taught, suggested, or implied by the applied prior art. For a prior art reference to anticipate in terms of 35 U.S.C. § 102, every element of the claimed invention must be identically shown in a single reference. *In re Bond*, 910 F.2d 831, 15 USPQ2d 1566 (Fed. Cir. 1990). There must be no difference between the claimed invention and the reference disclosure, as viewed by a person of ordinary skill in the field of the invention. *Scripps Clinic & Research Foundation v. Genetech, Inc.*, 927 F.2d 1565, 18 USPQ2d 1001, 18 USPQ2d 1896 (Fed. Cir. 1991). Absence from a cited reference of any element of a claim negates anticipation of that claim by the reference. *Kloster Speedsteel AB v Crucible, Inc.*, 230 USPQ 81 (Fed. Cir. 1986), *on rehearing*, 231 USPQ 160 (Fed. Cir. 1986).

3. Rejection under 102(e) over Jeffers et al., U.S. Pat. No. '510.

Claims 56-181 stand rejected under 35 U.S.C. § 102(e). (Office Action at 109.) The Examiner asserts that claims 56-181 are anticipated by U.S. Patent No. 4,739,510, issued to Jeffers et al. (Jeffers). Applicants assert that Jeffers is not available as prior art under 35 U.S.C. § 102(e) with respect to claims 56-181. Under 35 U.S.C. § 102(e), an issued patent filed in the United States prior to the invention by Applicants of the claimed subject matter may be relied upon to show anticipation. Jeffers was filed April 2, 1987, and was a continuation of Application No. 729,290, filed May 1, 1985. Applicants'

pending claims are entitled to the effective filing date of November 3, 1981, as discussed above in Part 1. Therefore, Jeffers was not filed prior to the invention by Applicants of the claimed subject matter. For at least these reasons, Applicants respectfully request the withdrawal of the rejection of claims 56-181 under 35 U.S.C. § 102(e).

I. Response to Rejections under 35 U.S.C. § 103

1. Rejection over Campbell et al. or Jeffers et al. in view of Applicants' U.S. Pat. Nos. '490 & '725.

Claims 56-181 stand rejected under 35 U.S.C. § 103(a). The Examiner asserts that claims 56-181 are unpatentable over Campbell et al. or Jeffers et al. in view of Applicants' own U.S. Patents Nos. 4,694,490, and 4,704,725. (Office Action at 118.) Applicants respectfully submit that Jeffers is not available as prior art as discussed above in Part H.3. Applicants respectfully submit that U.S. Patents Nos. 4,694,490 and 4,704,725 are not available as prior art as discussed above in Part H.1. The Examiner has failed to demonstrate that Campbell shows or suggests all the limitations of the pending claims as discussed above in Part H.2. The Examiner in asserting the instant rejection under 35 U.S.C. § 103(a) makes no attempt to provide any further reasons regarding why any claim limitation would be obvious in view of Campbell. For at least these reasons, Applicants submit that the Examiner has failed to establish a *prima facie* case of obviousness. Therefore, Applicants respectfully request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 103(a).

2. Rejection over WO 89/02682

Claims 56-181 stand rejected under 35 U.S.C. § 103(a). The Examiner asserts that claims 56-181 are unpatentable over WO 89/02682. (Office Action at 119.) WO 89/02682 is the international publication number of the Applicants' own international application published March 23, 1989. The specification of this international application substantially corresponds to the specification of the instant application. Claims 56-181

are entitled to the effective filing date of November 3, 1981, for the reasons discussed above in Part H.1. Therefore, this international application published March 23, 1989, is unavailable as prior art. Accordingly, Applicants request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 103(a).

3. Rejection over Campbell et al., U.S. Pat. No. 4,536,791.

The Office Action rejects Applicants' claims 56-181 over Campbell et al. stating that Campbell et al. teaches generation of text from a local text graphics generator for overlaying on the Campbell et al. display. The Office Action then states that the Campbell et al. teaching of text and video would render Applicants' language of "portions" which are either "sequentially," "concurrently" or "simultaneously" displayed as obvious as suitable descriptors. The Examiner in asserting the instant rejection under 35 U.S.C. § 103(a) makes no attempt to provide any reasons regarding why any claim limitation would be obvious in view of Campbell et al. For at least these reasons, Applicants submit that the Examiner has failed to establish a *prima facie* case of obviousness.

To establish a *prima facie* case of obviousness, three basic criteria must be met. First, there must be some suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art to modify the reference to combine the teachings. Second, there must be a reasonable expectation of success. Finally, the prior art reference (or references combined) must teach or suggest all the claim recitations. The teaching or suggestion to make the claimed combination and the reasonable expectation of success must both be found in the prior art, not based on Applicants' disclosure. *In re Vaeck*, 947 F.2d 488, 20 U.S.P.Q.2d 1438 (Fed. Cir. 1991). M.P.E.P. 706.02(j).

Additionally, the Office Action states that it would have been obvious to provide the various claimed displays in the organized and specifically recited manner for the

benefit of providing greater functionality to the subscriber. This statement lacks the proper motivation for establishing obviousness under 35 U.S.C. § 103 for at least the following reasons. First, “for the benefit of providing greater functionality to the subscriber” does not answer the question of whether the differences would have been obvious to one of ordinary skill in the art. This attempt at providing motivation fails to take into consideration the level of ordinary skill at the time of the invention. To determine whether greater functionality provides adequate motivation, the Examiner should take into consideration (among other things) the level of ordinary skill in the art, as expressly provided in M.P.E.P § 804 (II)B(1) and *Graham v. John Deere Co.*⁷ A proper motivation statement takes into consideration what would have been obvious to someone with ordinary skill in the art at the time of the invention. Without this determination, a modification cannot be deemed obvious for “greater functionality”.

Therefore, Applicants respectfully request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 103(a).

a) Applicants’ Claim 56

With respect to Applicants’ amended claim 56, Campbell et al. fails to teach, *inter alia*:

a method for receiving and processing data...for displaying a video presentation comprising a locally generated image and an image received from a remote video source; communicating one of said at least said first request and a second request to a remote data source; receiving from said remote data source said data to serve as a basis for displaying said video presentation;

⁷ 383 U.S.1, 148 USPQ 459 (1966).

processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and displaying said locally generated image at said video output device in conjunction with said image from said remote video source.

Campbell et al. teaches that the

text/graphics generator 118 includes a plurality of video switches which are used to bypass the text/graphics generator with the channel video. Optionally the video switches also permit the channel number display to be superimposed on the video signal of the channel which is being presented. (Column 9 lines 34-39.)

However, Campbell et al. fails to teach receiving from said remote data source said data to serve as a basis for displaying said video presentation, wherein the video presentation comprises a locally generated image with said image from said remote video source.

Applicants respectfully submit that the cited art does not anticipate claim 56 since Campbell et al. fails to disclose every element of the claimed invention, and Applicants respectfully request that the 35 U.S.C. § 102 rejection of claim 56 be withdrawn.

Claims 57-74 & 89-91 depends upon independent claim 56. As discussed *supra*, Campbell et al. fails to disclose every element of claim 56 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 57-74 & 89-91, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

b) Applicants' Claim 75

With respect to Applicants' amended claim 75, Campbell et al. fails to teach, *inter alia*,

a method of delivering a video presentation...said video presentation including a first video image and a second video image, said first video image received at said at

least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image;

receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;

receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation.

There is no teaching in Campbell et al. where a second image contains at least one datum that at least one of completes and supplements said first video image. The prompting screens generated by generator 118 and the channel numbers fail to contain a datum that either completes or supplements a first video image. Additionally, there is no teaching in Campbell et al. of a downloadable processor instruction capable of causing said at least one receiver station to generate locally and output said second video image. See above references and citations to Campbell et al. And finally, there is no teaching of a control signal that cause the execution of a downloadable processor instruction and to deliver the second video image.

Claims 76-79 depends upon independent claim 75. As discussed *supra*, Campbell et al. fails to disclose every element of claim 75 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 76-79, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

c) Applicants' Claim 80

With respect to Applicants' amended claim 80, Campbell et al. fails to teach, *inter alia*, an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video. There is no teaching in Campbell et al. of any transmitted signal that causes the converter 40 to display of a locally generated portion of a video presentation in conjunction with said transmitted video presentation.

Claims 81-83 & 92 depends upon independent claim 80. As discussed *supra*, Campbell et al. fails to disclose every element of claim 80 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 81-83 & 92, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

d) Applicants' Claim 84

With respect to Applicants' amended claim 84, Campbell et al. fails to teach, *inter alia*,:

wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction;

wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor

instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited processor instruction and the functionality of the discrete signals.

Claims 85-88 depends upon independent claim 84. As discussed *supra*, Campbell et al. fails to disclose every element of claim 84 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 85-88, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

e) Applicants' Claim 93

With respect to Applicants' amended claim 93, Campbell et al. fails to teach, *inter alia*,

organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;

passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;

responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;

generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and

outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information into processor instructions which cause the generation of an image to be output to replace said only said portion of said video image.

Claims 94-109 depends upon independent claim 93. As discussed *supra*, Campbell et al. fails to disclose every element of claim 93 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 94-109, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

f) Applicants' Claim 110

With respect to Applicants' claim 110, Campbell et al. fails to teach, *inter alia*, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;

receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited processor instruction comprised of information organized from said information contained in said first discrete signal and information contained in a second discrete signal, and a control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction.

Claims 111-115 depends upon independent claim 110. As discussed *supra*, Campbell et al. fails to disclose every element of claim 110 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 111-115, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

g) Applicants' Claim 116

With respect to Applicants' amended claim 116, Campbell et al. fails to teach, *inter alia*:

wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction;

receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information

contained said first discrete signal with said information contained in said second discrete signal.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited displaying a locally generated image in conjunction with said video in response to at least one processor instruction, and the processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal. Additionally, there is no reference to organizing said information contained said first discrete signal with said information contained in said second discrete signal

Claims 117-122 depends upon independent claim 116. As discussed *supra*, Campbell et al. fails to disclose every element of claim 116 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 117-122, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

h) Applicants' Claim 123

With respect to Applicants' amended claim 123, Campbell et al. fails to teach, *inter alia*,

wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device;

receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;

said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited code and identifier, instruct signal to generate locally and output said second image of said video presentation for delivery in conjunction with said first image, and the first discrete signal including only partial information of said one of a code and an identifier.

Claims 124-141 depends upon independent claim 123. As discussed *supra*, Campbell et al. fails to disclose every element of claim 123 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 124-141, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

i) Applicants' Claim 142

With respect to Applicants' amended claim 142, Campbell et al. fails to teach, *inter alia*,

organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;

passing at least one processor instruction from or within said at least one processor. said at least one processor instruction comprising said organized information from said step of organizing;

generating only a portion of said video image based on said step of responding to said at least one processor instruction; and

outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information into a processor instruction and generating and outputting only a portion of said video image with respect to the processor instruction.

Applicants respectfully submit that the cited art does not anticipate claim 142 since Campbell et al. fails to disclose every element of the claimed invention, and Applicants respectfully request that the 35 U.S.C. § 102 rejection of claim 142 be withdrawn.

j) Applicants' Claim 143

With respect to Applicants' amended claim 143, Campbell et al. fails to teach, *inter alia*,:

organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;

generating a signal based on said processor instructions; and

outputting at least a portion of said video presentation based on said generated signal.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information in a first and second discrete signal into processor

instructions and generating and outputting a portion of said video presentation based on said generated signal.

Claims 144-151 depends upon independent claim 143. As discussed *supra*, Campbell et al. fails to disclose every element of claim 143 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 144-151, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

k) Applicants' Claim 152

With respect to Applicants' amended claim 152, Campbell et al. fails to teach, *inter alia*, receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited control signal operative at the receiver station to direct said video image to said output device, designate a processor ... or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image.

Claims 153-156 depends upon independent claim 152. As discussed *supra*, Campbell et al. fails to disclose every element of claim 152 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 153-156 and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

l) Applicants' Claim 157

With respect to Applicants' amended claim 157, Campbell et al. fails to teach, *inter alia*, an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited instruct signal effective to generate and output a local image in conjunction with said video image.

Claims 158-161 depend upon independent claim 157. As discussed *supra*, Campbell et al. fails to disclose every element of claim 157 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 15-161, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

m) Applicants' Claim 162

With respect to Applicants' amended claim 162, Campbell et al. fails to teach, *inter alia*, said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first

of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited said first of said plurality of discrete signals which enable the processing of code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals.

Claims 163-166 depend upon independent claim 162. As discussed *supra*, Campbell et al. fails to disclose every element of claim 162 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 163-166, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

n) Applicants' Claim 167

With respect to Applicants' claim 167, Campbell et al. fails to teach, *inter alia*, organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited step of organizing information into a processor instruction and the step of displaying a second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen.

Claims 168-170 depend upon independent claim 167. As discussed *supra*, Campbell et al. fails to disclose every element of claim 167 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 168-170, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

o) Applicants' Claim 171

With respect to Applicants' amended claim 171, Campbell et al. fails to teach, *inter alia*,

at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed

full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image;

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station; and

wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited second completed full-screen video graphic image, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen, and receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction.

Claims 172-174 depends upon independent claim 171. As discussed *supra*, Campbell et al. fails to disclose every element of claim 171 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 172-174, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

p) Applicants' Claim 175

With respect to Applicants' claim 175, Campbell et al. fails to teach, *inter alia*, at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image; and

one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image.

Claim 176 depends upon independent claim 175. As discussed *supra*, Campbell et al. fails to disclose every element of claim 175 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claim 176, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

q) Applicants' Claim 177

With respect to Applicants' claim 177, Campbell et al. fails to teach, *inter alia*, one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen.

Claim 178 depends upon independent claim 177. As discussed *supra*, Campbell et al. fails to disclose every element of claim 177 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claim 177, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

r) Applicants' Claim 179

With respect to Applicants' claim 179, Campbell et al. fails to teach, *inter alia*:

organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;

responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;

passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and

displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image.

Campbell et al. fails to teach and the Office Action fails to address Applicants' above recited organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal, and passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image, and displaying said second completed full-screen video graphic image at said video monitor.

Claims 180-182 depends upon independent claim 179. As discussed *supra*, Campbell et al. fails to disclose every element of claim 179 and thus, *ipso facto*, Campbell et al. fails to anticipate dependent claims 180-182, and therefore, this rejection should be withdrawn and the claims be permitted to issue. If an independent claim is nonobvious under 35 U.S.C. 103, then any claim depending therefrom is nonobvious. *In re Fine*, 837 F.2d 1071, 5 USPQ2d 1596 (Fed. Cir. 1988).

4. Rejection over Jeffers et al.

Claims 56-181 stand rejected under 35 U.S.C. § 103(a). The Examiner asserts that claims 56-181 are unpatentable over Jeffers et al. (Office Action at 120.) Applicants respectfully assert that Jeffers is not available as prior art as discussed above in Part H.3. Accordingly, Applicants respectfully request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 103(a).

5. Rejection over Jeffers et al. in view of Examiner's Official Notice.

Claims 56-181 stand rejected under 35 U.S.C. § 103(a). The Examiner asserts that claims 56-181 are unpatentable over Jeffers et al. in view of the Examiner's Official Notice. (Office Action at 120.) Applicants assert that Jeffers is not available as prior art as discussed above in Part H.3. Applicants further assert that the Examiner's Official Notice is improper. The Examiner asserts that "various claimed displays of 'locally generated graphics with remotely generated video were conventionally well known with respect to Direct TV like art.'" (Office Action at 120.) Applicants traverse this statement by the Examiner. The Examiner may take Official Notice of facts that are capable of such instant and unquestionable demonstration as to defy dispute. *In re Ahlert*, 424 F.2d 1088, 165 U.S.P.Q. 418, 420 (C.C.P.A. 1970). Assertions of technical facts in areas of esoteric technology must always be supported by citation to some reference work recognized as standard in the pertinent art. *Id.* The Examiner's assertion is not capable of such instant and unquestionable demonstration as to defy dispute. To the contrary, the time at which the knowledge asserted by the Examiner to be well known became public is in dispute. Applicants acknowledge that PMC (the assignee of the instant application) alleges that DirecTV infringes one or both of U.S. Patents Nos. 5,335,277 and 5,233,654, both of which were issued to Applicants. The instant application claims priority from the

applications that matured into these patents. The specification of the instant application is substantially identical to the specifications of both of these patents. Contrary to the implication by the Examiner, these facts fail support the Examiner's assertion that displays of locally generated graphics with remotely generated video were well known at the time of Applicant's filing date. Applicants assert that the Examiner's Official Notice is incorrect and unsupported. Therefore, the Examiner's assertion is insufficient to serve as the basis for a rejection under 35 U.S.C. § 103(a). Accordingly, Applicants request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 103(a).

6. Rejection over Campbell et al. in view of Zaboklicki.

Claims 56-181 stand rejected under 35 U.S.C. 103(a) as being unpatentable over Campbell et al. in view of Zaboklicki.

Zaboklicki discusses in general terms (as best understood by Applicants) an "interactive television system" (i) wherein "a local central unit is provided in the home television receivers on the receiver side; that central unit switches the data selection systems on the basis of the television viewer's answer and on the basis of the centrally transmitted digital processing program for the television segments (transmission fragments)" (English language translation of DE 29 04 981 A 1 at 10 ll. 13 - 18); (ii) with "individual variants of ... additional information ... passed on in the form of acoustic or sound signals in the television receiver in the infrared band to the individual infrared receivers" (*id.* at 11 ll. 2 - 7); (iii) with "participation of the television viewer in the centrally transmitted telecast in such a way that the output signals of the local central unit in the viewfinder of the television camera turn on the contours of the person is provided for by the director [whereby the shape of the viewer contained in these contours is blended into the main content]" (*id.* at page 12, lines 8 - 13); and (iv) wherein, "[i]n the case of telecasts where an answer or the opinion of the television viewers is desired... the viewer's answer is put out parallel and converted into telephone signals... introduced into

the subscriber telephone line... [and] supplied to the monitor in the television studio after statistical processing" (*id.* at 12, l. 13 through p. 13 l. 3).

In fact, Zaboklicki is so vague and indefinite in its description of the technology that virtually any reliance on the publication as prior art in the instant application can only be based on speculation and conjecture about the functionalities alleged to be provided by, or the method of operation of, the Zaboklicki system. Zaboklicki is not an enabling publication.

Applicants note the PTO has supplied and relies on a translation of German Patent publication No. DE 2904981 A 1 in formulating the rejections of the subject claims. Applicants have found that the applied German Patent publication is based on an earlier Polish patent application No. PL 204525 A filed February 9, 1978. In addition to the German publication, the earlier Polish application also forms the basis for French patent publication FR 2417226 A published October 12, 1979 and British patent publication GB 2016874 A published September 26, 1979.

After careful review of the Polish application and British publication, it is self evident that neither the translation provided by the PTO nor the British patent publication (presumably prepared or approved by Zaboklicki) indicates or suggests any method of operation of, or relationship between, the blocks shown in the various figures. In fact, it is difficult or impossible to determine what functions are being performed by the blocks shown in the various figures because many of the labels are not descriptive, failing to articulate or indicate the intended function. The written description does not cure this defect of the disclosure, failing to describe the functions or the interactions between the blocks. Examples of labels inadequately describing the structure of and function performed by the corresponding blocks are included in the following table.

Ref. No	Label	Description	
		English Language Translation of German Patent Publication	British Patent Publication
4	The circuit for the prescreening of information items for television viewers	preliminary screening of the information items for the television viewer	distributes the information for televiewers
5	The control circuit	None	output of control system 5 is additionally fed to the circuits 8 and 10 and is also applied to a circuit 11 for restoring the music signal
6	The central unit (the processor, for example, integrated microprocessor)	the output signals of the central unit 6 control a data selection circuit 8; energizes a sound signal switching unit 20 in at least one additional sound channel	output of circuit 3 is fed to a processor 6 ... [which] is also fed with signals representing the televiewer's answer from the circuit 2 [and] transmits a digital programme of manipulation, televiewers' answers and the successive identification data of ... individual fragments of the broadcast to a store or memory (RAM) 7; keyboard 12 feed into the processor 6 and the latter output to a transmitter of infra-red signals 13 which produces a remote control signal at 14; Digital data and audio signals with different variants of additional information are applied at 15 to the input of a receiver 16 of infra-red signals having an output in the form of digital data fed over line 17 to processor 6; switching-on of the selected audio channel as determined by the processor 6
10	The circuit for video signal conversion and image illumination	used to convert video signals and for image illumination	for converting video signals and displaying a picture
11	The circuit for sound signal restitution	circuit for sound signal restitution	for restoring
15	The digital data and the phonics with the different variants of additional information	None	input of receiver 16
19	The command for sound turn-on in the corresponding channel	command for a sound signal of a corresponding channel that is supplied to a circuit 20 for turning on the selected sound channel	commands to switch-on the audio signal from a specific channel are fed over the command line 19 from the processor 6 to the receiver 20
27	The switchover of the television channels for the prescreening of the corresponding fragments of a telecast	line for switching over television channels for preliminary screening of the corresponding fragments of a telecast	television receiver 54 is fed over line 53 with control signals from the remote control signal receiver 52 and over the one 27 from the output system 49 of the processor

Ref. No	Label	Description	
		English Language Translation of German Patent Publication	British Patent Publication
28	The short term of call signal transmission during which the answer is delayed	control signal for the delay of the answer, which represent the short span of time during which call signal transmission takes place and during that time span, the answer is delayed.	[Control system 32] is also fed via 28 with a short delay signal for sending the dialing signals when the answer is postponed
29	The prefix generator for transmission announcement of the television viewer's answer	for a transmission announcement of the television viewer's answer with a subscriber generator 30 and with a circuit 31 to generate the television viewer's answer	prefix generator for announcing the transmission of the televiewer's answer
35	The circuit for the introduction of the initial data of the television viewers	serves to put in initial data from the television viewers	circuit for introducing the televiewer's answers
36	The circuit for the prescreening of the digital data from the video signal	causes the preliminary screening of the digital data of the video signal	system for distributing the digital data from the video signals
38	The multiplexer circuit	supplies a signal for the subscriber telephone line 33.	Output from the units 29 and 30, 31 and 32 are applied to a multiplexer 38 whose output 46 is in turn fed to a subscriber telephone line
40	The circuit for the prescreening of the digital handling program (telesoftware) and the identification data of the individual fragments of the telecast	for the prescreening of digital processing programs and the identification data of the individual transmission fragments with the input circuits 39	system for separation of the telesoftware and the identification data of the individual fragments of the broadcast
41	The data selection circuit of the circuit for the comparison of the addresses of the teletext information items	constitutes a data selection circuit or a circuit for the comparison of the addresses of text information, for example, page numbers. Local central unit 6 switches over the data selection circuits 41 as a result of the answers from a television viewer and the digital processing programs which are supplied to the central unit 39 by the output circuit	information selections system or a system for comparing the address of the teletext information, for example the page number, in conjunction with the local processor 6 for switching over the information selection system depending upon the televiewers answer and on the telesoftware
42	generator of the alphanumeric and graphic symbols	generator for alphanumeric and graphic symbols	alphanumeric and graphic character generator
43	circuit for turning on one of the additional sound channels in the television receiver (54)	switch-on or for the operation of additional sound channels of a television receiver 54	audio channel switch for switching on the sound signal in the television receiver
45	multiplexer circuit	multiplexer circuit	multiplexer of the receiver
46	signal output for the subscriber telephone line	None	none

Ref. No	Label	Description	
		English Language Translation of German Patent Publication	British Patent Publication
47	circuit for the prescreening of the symbols for the control of the image illumination function	prefiltering or prescreening of the symbols for the control of image illumination	system for distributing characters to the display control
48	output circuit for symbols	output circuit	character output system
51	multiplexer circuit in the viewfinder of the television camera for the application of the graphic symbols on the image	multiplexer circuit 51 in the viewfinder of a television camera is used to project the graphic symbols into the image of receiver 54 of the television camera that furthermore is connected to a receiver 52 for a remote-control signal	multiplexer system
54	television receiver with at least one additional sound channel	Receiver	television receiver including an audio channel switch 43 for switching on the sound signal I the television receive and an output circuit 55 for the video signal
56	teletext decoder with the additional data output after hamming decoder	a video text decoder 56 with an additional data output (hamming decoder)	teletex decoder having an additional data output behind the Hamming decoder comprising a control system 26, a system 36 for distributing the digital data from the video signals, a system 40 for separation of the telesoftware and the identification data of the individual fragments of the broadcast, an information selection system 41, (or a system for comparing the address of the teletex information, for example the page number, in conjunction with the local processor 6 for switching over the information selection system depending upon the viewers answer and upon the telesoftware), an RAM memory 44, a system 57 for distributing control characters, (for example no display), an alphanumeric and graphic character generator 42, a system 47 for distributing characters to the display control and a character output system 48.
57	circuit for the prescreening of the control symbols, for example, a command: do not illuminate	A circuit 57 in decoder 56 is used for the prefiltering of control signals or control commands (For example, do not illuminate.)	system for distributing control characters, (for example no display)

It is established that prior art must be enabling. *Rockwell Int'l. Corp. v. United States*, 147 F.3d 1358, 1365, 27 U.S.P.Q.2d 1027 (Fed. Cir. 1998). "In order to render a

claimed apparatus or method obvious, the prior art must enable one skilled in the art to make and use the apparatus or method.” *Beckman Industries, Inc. v. LKB Produkter AB*, 892 F.2d 1547, 1551, 13 U.S.P.Q.2d 1301, 1304 (Fed. Cir. 1989) (citing *In re Payne*, 606 F.2d 303, 314, 203 U.S.P.Q. 245, 255 (CCPA 1979)). Accordingly, in *Beckman*, held as a correct statement of the law were jury instructions that stated, “References relied upon to support a rejection for obviousness must provide an enabling disclosure. That is to say, they must place the claimed invention in the possession of the public.” *Id.* at 1550-51, 13 U.S.P.Q.2d at 1303-4. The Federal Circuit has observed that “even if the claimed invention is disclosed in a printed publication, that disclosure will not suffice as prior art if it was not enabling.” *In re Donohue*, 766 F.2d 531, 533, 226 U.S.P.Q. 619, 621 (Fed. Cir. 1985) (citing *In re Borst*, 345 F.2d 851, 855, 145 U.S.P.Q. 554, 557 (C.C.P.A. 1965), cert. denied, 382 U.S. 973, 148 U.S.P.Q. 771 (1966) (“the disclosure must be such as will give possession of the invention to the person of ordinary skill”)). See also *In re Epstein*, 32 F.3d 1559, 1568, 31 U.S.P.Q.2d 1817, 1823 (Fed. Cir. 1994); *Reading & Bates Construction Co. v. Baker Energy Resources Corp.*, 748 F.2d 645, 651-52, 223 U.S.P.Q. 1168, 1173 (Fed. Cir. 1984); *Preemption Devices, Inc. v. Minnesota Mining & Manufacturing Co.*, 732 F.2d 903, 906, 221 U.S.P.Q. 841, 843 (Fed. Cir. 1984).

If anything is clear, it is that Zaboklicki does not place the technology of Applicants’ invention into the hands of the public. The reference to Zaboklicki at most presents some block diagrams which, as best understood, are directed to the four functions previously outlined. The details of these functionalities or how they are accomplished are not described in sufficient detail or with sufficient clarity to constitute an enabling disclosure.

Additionally, the Office Action states that it would have been obvious modify Campbell et al. with Zaboklicki for the benefit of greater display functionality at the user station. This statement lacks the proper motivation for establishing obviousness under 35 U.S.C. § 103 for at least the following reasons. First, “for the benefit of greater display

functionality at the user station” does not answer the question of whether the differences would have been obvious to one of ordinary skill in the art. This attempt at providing motivation fails to take into consideration the level of ordinary skill at the time of the invention. To determine whether greater functionality provides adequate motivation, the Examiner should take into consideration (among other things) the level of ordinary skill in the art, as expressly provided in M.P.E.P § 804 (II)B(1) and *Graham v. John Deere Co.*⁸ A proper motivation statement takes into consideration what would have been obvious to someone with ordinary skill in the art at the time of the invention. Without this determination, a modification cannot be deemed obvious for “greater functionality”.

Therefore, Applicants respectfully request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 103(a).

7. Rejection over Jeffers et al. in view of Zaboklicki.

Claims 56-181 stand rejected under 35 U.S.C. § 103(a). The Examiner asserts that claims 56-181 are unpatentable over Jeffers et al in view of Zaboklicki. (Office Action at 120.) Applicants assert that Jeffers is unavailable as prior art as discussed above in Part H.3. Applicants assert that Zaboklicki is insufficient as prior art as discussed above in Part 6. For at least these reasons, Applicants request the withdrawal of this rejection of claims 56-181 under 35 U.S.C. § 103(a).

J. Response to Examiner’s Administrative Requirement

Applicants respectfully traverse the requirements imposed by the Examiner in the Office Action at page 128.

The Examiner requires Applicants to either:

⁸ 383 U.S.1, 148 USPQ 459 (1966).

- (1) file terminal disclaimers in each of the related 329 applications terminally disclaiming each of the other 329 applications; or
- (2) provide an affidavit attesting to the fact that all claims in the 329 applications have been reviewed by applicant and that no conflicting claims exist between the applications; or
- (3) resolve all conflicts between claims in the related 329 applications by identifying how all the claims in the instant application are distinct and separate inventions from all the claims in the above identified 329 applications.

In addition, Examiner states that failure to comply with any one of these requirements will result in abandonment of the application.

Applicants traverse this requirement for the reasons stated in Section II C of the Amendment and Request for Reconsideration filed September 18, 1998. Further, Applicants have fully responded to the re-imposition of this requirement in the Petition To The Commissioner Under 37 C.F.R. § 1.181 filed March 7, 2000, which requests, *inter alia*, that this improper requirement be withdrawn.

K. Response to Obviousness-Type Double Patenting Rejection

Applicants respectfully request that the Examiner reconsider and withdraw his rejection based on obviousness-type double patenting on two separate grounds.

1. The Examiner has totally confused and misapplied the established law of double patenting and, further, has failed to follow the mandates of the Manual of Patent Examining Procedure as to double patenting rejections.
2. The Examiner has also failed to analyze the pending claims on a limitation-by-limitation basis to demonstrate that no patentable distinctions exist between the pending claims and those in the issued Harvey patents.

1. PTO Assertions in Office Action mailed January 7, 2000

The Examiner has rejected claims 56-181 of the application under the judicially created doctrine of obviousness-type double patenting as being unpatentable over claims 1-13 of U.S. Patent No. 4,684,490 (Harvey I); claims 1-5 of U.S. Patent No. 4,704,725 (Harvey II); claims 1-25 of U.S. Patent No. 4,965,825 (Harvey III); claims 1-26 of U.S. Patent No. 5,109,414 (Harvey IV); claims 1-71 of U.S. Patent No. 5,233,654 (Harvey V); and claims 1-56 of U.S. Patent No. 5,335,277 (Harvey VI).

In the Office Action at pages 130-34, the Examiner takes the position that if two claims in separate applications are supported by the same embodiment of the applications' common specification, then the PTO has demonstrated a *prima facie* basis for a double patenting rejection of the obviousness type. More specifically, the Examiner legally concludes that under the judicial doctrine of obviousness-type double patenting, a terminal disclaimer is necessary, "since the pending claims merely reflect an obvious variant of the '81 disclosed WSW monopoly for which Applicants have long enjoyed a monopoly." (Office Action at 131.) The Examiner provides no authority for this allegedly new ground for obviousness-type double patenting other than his own bald statement.

In the Office Action at pages 134-145, the Examiner rejects claims 56-181 under obviousness-type double patenting as being unpatentable over any single claim or combination of claims "in view of each combination of art described within this action." (Office Action at 135.) The Examiner attempts to assert a catch-all rejection by incorporating all arguments and allegations discussed throughout the one hundred and forty seven (147) page Office Action. Again, the Examiner provides no authority for this sweeping new ground for rejecting claims under obviousness-type double patenting.

The Examiner's application of obviousness-type double patenting standard represents an erroneous and misapplied interpretation of existing case law and is contrary to patent examining procedure. First, the Examiner has confused and misapplied the

This Page Blank (uspto)

established law of double patenting and has failed to follow the mandates of the M.P.E.P. as to double patenting rejections. Secondly, the Examiner has also failed to analyze the pending claims on a limitation-by-limitation basis to demonstrate that no patentable distinctions exist between the pending claimed and those issued in the Harvey patents as required by the M.P.E.P.

Based on the following discussion, Applicants respectfully request the withdrawal of these rejections.

2. The Scope of the Double Patenting Doctrine

The prohibition against double patenting is a judicial doctrine based on the language of 35 U.S.C. § 101, which specifies that an inventor who invents “any new and useful process, machine, manufacture, or composition of matter...may obtain a patent therefor.” In *Miller*⁹, the U.S. Supreme Court held the term “a patent” to mean, “two valid patents for the same invention cannot be granted either to the same or to a different party.”¹⁰ Therefore, the claims in a second patent must be patentably distinct from the claims in a first patent or the second patent would be an improper extension of the first.

As the preclusion is to obtaining two patents on the same invention or an obvious modification of the same invention, the sole question is whether by examining the scope of the claims, one has attempted to claim the same subject matter twice, or an obvious variation. No prohibition exists against a second patent on subject matter that is disclosed but not claimed in the first patent.

Under 35 U.S.C. § 120, a patent applicant may submit additional claims in a subsequent application which are supported by the disclosure in the original applications' specification. A proper continuation application and its original application are considered “parts of the same transaction, and both as constituting one continuous

⁹ *Miller v. Eagle Mfg. Co.*, 151 U.S. 186 (1894).

¹⁰ *Id.* at 197.

application, within the meaning of the law.”¹¹ Furthermore, 35 U.S.C. § 120 does not place a definite time limit on filing a continuing application. Rather, all that is required to preserve an earlier effective filing date as to common subject matter is copendency or a continuous chain of copendency.

The double patenting doctrine prevents an extension of a patent term which would occur if successive patents were allowed on the same invention or obvious variants. However, if two patents contain the same disclosure, but claim different inventions or nonobvious variations, double patenting does not exist.

3. Patent Office Procedure

The U.S. Patent and Trademark Office (“PTO”) has specified a procedure in the Manual of Patent Examining Procedure (M.P.E.P.) for Examiners to follow in establishing a *prime facie* case of double patenting. In determining whether a proper basis exists for a double patenting rejection, the Examiner must determine whether:

1. A double patenting rejection is prohibited by the third sentence of 35 U.S.C. § 121 related to divisional applications,
2. A statutory basis exists (i.e., whether same-invention double patenting is present), or
3. A non-statutory basis exists (i.e., whether obviousness-type double patenting is present).¹²

Assuming the application is not a divisional application, the Examiner must establish in step 2 that the same invention is being claimed twice. The Court specified in *In re Vogel*, 422 F.2d 438, 164 U.S.P.Q. 619 (C.C.P.A. 1970), that in determining same-invention double patenting analysis, one must ask “is the same invention being claimed twice?...[The] “invention” here means what is defined by the claims, whether new or old,

¹¹ *In re Hogan*, 449 F.2d 595, 603 (CCPA 1977)(quoting *Godfrey v. Earnes*, 68 U.S. 317, 325-6 (1864)).

¹² M.P.E.P. § 804.

obvious or unobvious....By the "same invention" we mean identical subject matter."¹³

The court stated "that claims may be differently worded and still define the same invention."¹⁴ In conclusion, the court found "the only objective test" for same-invention double patenting as,

whether one of the claims could be literally infringed without literally infringing the other. If it could be, the claims do not define identically the same invention.¹⁵

If there is no same-invention double patenting, then the Examiner must establish in step 3 obviousness-type double patenting wherein the grant of a patent with the claims in the application would unjustly extend the rights granted by the first patent.

4. Nonstatutory Double Patenting

In defining nonstatutory double patenting, the M.P.E.P. provides three types of nonstatutory-type double patenting based on the judicial doctrine, which include one-way obviousness, two-way obviousness¹⁶, and nonobviousness rejections.¹⁷

Under the M.P.E.P. requirements, if the application at issue is the later filed application, only a one-way determination of obviousness is needed to resolve the issue of double patenting. The issue to be determined is whether the invention defined in a claim in the application is an obvious variation of the invention defined in a claim of the patent.

¹³ *In re Vogel*, 422 F.2d at 441.

¹⁴ *Id.*

¹⁵ *Id.*

¹⁶ A two-way obviousness double patenting rejection arises in the specific instance where the claims of a patent application are being compared with the claims of a later filed but earlier issued patent. This is not the case with respect to the present double patenting rejection.

¹⁷ M.P.E.P. § 804. Nonobviousness-type double patenting rejections arise in circumstances as described in *In re Schneller*, 397 F.2d 350, 158 USPQ 210 (CCPA 1968). With respect to the instant application, a nonobviousness-type double patenting rejection was made on February 6, 1997, and withdrawn in the Office Action mailed on March 31, 1998.

See, e.g., *In re Berg*, 46 U.S.P.Q.2d 1226 (Fed. Cir. 1998). The M.P.E.P mandates that unless a claimed invention in the application is obvious over a claimed invention in the patent, an Examiner should make no double patenting rejection of the obviousness-type. Thus, the sole issue is the scope of the inventions as defined by the claim language in the patent and later filed application.

a) Standard for Determining One-Way Obviousness-Type Double Patenting

*In re Kaplan*¹⁸, the Federal Circuit specified that an obviousness-type double patenting rejection rests on the prohibition against issuance of a second patent that would continue protection, beyond the expiration date of the first patent, or a mere variation of the previous patented invention that would have been obvious to those of ordinary skill in the relevant art.

Thus, in establishing a *prima facie* case of obviousness-type double patenting, the Examiner must,

1. Identify the inventions claimed in the claims under consideration and in the patent claims,
2. Establish that any variation(s) between the inventions claimed in the claims under consideration and the earlier-issued patent claims would have been obvious to person of ordinary skill in the art, and
3. Establish a *prima facie* case of obviousness.¹⁹

To summarize, the Examiner must show that (1) the inventions claimed (2) are not patentably distinct based on (3) a *prima facie* showing of obviousness. Instead, the

¹⁸ *In re Kaplan*, 789 F.2d 1574, 229 USPQ 678 (Fed. Cir. 1986).

¹⁹ See *In re Longi*, 759 F.2d 887, 225 USPQ 645, 651 (Fed. Cir. 1985) (Examiner must provide *prima facie* case of obviousness for obviousness-type double patenting rejection. The burden then shifts to the Applicant to rebut the *prima facie* case).

Examiner has provided bald statements that obvious variations exist. The mere finding that the claims themselves are obvious variations, without establishing that the alleged variations would have been obvious, cannot properly support an obviousness-type double patenting rejection.

In the Office Action under paragraphs 29 and 30, the Examiner has failed to establish a *prima facie* showing of obviousness-type double patenting in the rejection of claims 56-181. In particular, the Examiner has not identified the scope of the inventions of the instant application and the patents as determined by the claims. Secondly, the Examiner has not positively identified any variations in the claims of the instant application and the claims of the patent. Examiner has provided broad allegations that obvious variants exist, but fail to specifically state these allegedly obvious variants. Thirdly, the Examiner has not shown a *prima facie* case of obviousness under the requirements of 35 U.S.C. § 103. The Examiner has not indicated proper motivation in making the alleged obvious modifications. Since no motivation is provided, it may follow that the variations are not obvious. Moreover, monopolies would not be extended on the same claimed invention.

(1) Identifying the Inventions Claimed

(a) Scope of the Inventions as Defined by the Claim Language

The C.C.P.A. in *In re Vogel*²⁰ summarized this step by asking, “does any claim in the application define merely an obvious variation of an invention disclosed and claimed in the patent?”²¹ The analysis is based on what the claim defines, and not merely the claim language itself. This first step in the analysis should not focus on what the claim

²⁰ *In re Vogel*, 422 F.2d 438, 164 USPQ 619.

²¹ *Id.*, 164 USPQ at 622.

language *discloses*, but on rather what the claim language *defines*.²² As noted by the Federal Circuit,

it is important to bear in mind that comparison can be made only with what invention is *claimed* in the earlier patent, paying careful attention to the rules of claim interpretation to determine what invention a claim *defines* and not looking to the claim for anything that happens to be mentioned in it *as though it were a prior art reference*.²³

...

[T]he fundamental rule of claim construction, that what is claimed is what is *defined by the claim taken as a whole*, every claim limitation...being material²⁴

...

[P]atent claims are looked to only see what *has been patented*, the subject matter which *has been protected*, not for something one may find to be disclosed by reading them²⁵

Rather than identifying the scope of the inventions as defined by the claims, the Examiner has assumed an obviousness-type double rejection based on two claims in separate applications supported by the same embodiment of the applications' common specification, as set forth in paragraph 29. The basis for the Examiner's obviousness-type double patenting rejection is premised on a common embodiment. There is no statutory basis for this improper interpretation of obviousness-type double patenting.

The Examiner's "same embodiment" basis for obviousness-type double patenting is erroneous for at least the following reasons. First, two claims in two separate

²² *General Foods Corp. v. Studiengesellschaft Kohle mbh*, 972 F.2d 1272, 23 USPQ 1893, 1845 (Fed. Cir. 1992).

²³ *Id.*, 972 F.2d at 1280.

²⁴ *Id.*

²⁵ *Id.* citing *In re Aldrich*, 398 F.2d 855, 859, 158 USPQ 311, 314 (CCPA 1968).

applications may find support in the same embodiment while claiming inventions that are patently distinct. An embodiment as described by a common specification and drawings may fully disclose a wide range of details and limitations. However, it may not follow that separate claims, which are supported by a common embodiment, are also identical in scope, as assumed by the Examiner. Second, by relying on a common embodiment, the Examiner has improperly treated the specification as prior art. Finding a claimed invention to be an obvious variation of patented claims by treating the patent disclosure as though it is prior art has been repeatedly held as impermissible.²⁶ The use of an applicant's invention disclosure as prior art against him is improper.²⁷ By broadly rejecting pending claims under obviousness-type double patenting without analyzing the claims of the inventions, the Examiner has misapplied and confused the law of obviousness-type double patenting.

(b) Proper Use of Specification

Because the obviousness-type double patenting rejection requires claim interpretation, the Examiner may use the specification in a limited capacity to assist in interpreting what the claim language defines. The patent disclosure cannot be used as prior art, but the disclosure can be used to (1) determine the meaning of terms in a claim and may also be used as required to (2) answer the above question, "whether the claim in the application defines merely an obvious variation of the invention disclosed and claimed in the patent."²⁸ With respect to "the invention disclosed and claimed in the patent," the Federal Circuit stated in *Vogel*,

²⁶ *In re Kaplan*, 229 USPQ at 683.

²⁷ *Id.*

²⁸ *In re Vogel*, 422 F.2d at 441.

We recognize that it is difficult, if not meaningless, to try to say what is or is not an obvious variation of a claim. A claim is a group of words defining only the boundary of the patent monopoly....The disclosure, however, sets forth at least one tangible embodiment within the claim, and it is less difficult and more meaningful to judge whether that thing has been modified in an obvious manner. It must be noted that this use of the disclosure is not in contravention of the cases forbidding its use as prior art, nor is it applying the patent as a reference under 35 U.S.C. § 103, since only the disclosure of the invention claimed in the patent may be examined.²⁹

Therefore, it is proper to identify the invention claimed in the patent by using *exclusively only the portion(s) of the disclosure supporting the claimed invention*. Alternately, it is improper to make a double patenting rejection when the rejection relies on specification support other than the specific portion(s) of the disclosure supporting the claimed invention.

It has been repeatedly held that use of disclosure of a patent cited in support of a double patenting rejection cannot be used as through it were prior art, even where the disclosure is found in the claims. *See, e.g., Braat*, 937 F.2d at 594 n.5, 19 U.S.P.Q. at 1293 n.5 (“The patent disclosure must not be used as prior art”); *Vogel*, 422 F.2d at 442, 164 USPQ at 622 (in considering obviousness-type double patenting, “the patent disclosure may not be used as prior art”); *In re Plank*, 399 F.2d 241, 242, 158 U.S.P.Q. 328, 329 (C.C.P.A. 1968) (“Its claims are used as the basis for a double patenting rejection. It is not a prior art reference”); *In re Aldrich*, 398 F.2d 855, 859, 158 U.S.P.Q. 311, 314 (C.C.P.A. 1968) (“[P]atent claims are looked to only to see what has been patented, the subject matter which has been protected, not for something one may find to be disclosed by reading them.”)

²⁹ *Id.*, 422 F.2d at 442.

In the instant case, the Examiner has improperly relied on the specification in making the obviousness-type double patenting rejection. Applicants have previously alleged that all of the pending claims 58-181 are 'fully supported' by the '81 Wall Street Week embodiment'. Whether support is provided for the claim language is an issue separate from the scope of the claims in the determination of a double patenting rejection. The Examiner has confused the issue of claim support with the issue of claim interpretation in determining whether obviousness-type double patenting exists. While Applicants assert that claims 58-181 are fully supported by the '81 WSW embodiment, this assertion may not be used to construe the scope of the invention as defined by the claims. Claim interpretation is limited to what the claim language defines as the scope of the invention. It is clear that the Examiner has improperly imported the entire '81 Wall Street Week embodiment' into the scope of claims 56-181 in making the obviousness-type double patenting rejections. By doing so, the Examiner has relied on specification support other than the specific portions of the disclosure supporting the claimed invention. Applicants have failed to follow the mandates as expressed in the M.P.E.P. thereby failing to establish a *prima facie* case of double patenting of the obviousness-type.

According to *In re Vogel*, one must first "determine how much of the patent disclosure pertains to the invention claimed in the patent" because only "[t]his portion of the specification supports the patent claims and may be considered." The Examiner has disregarded this critical step in his analysis of the obviousness-type double patenting rejection. The Examiner instead takes the liberty to improperly incorporate the entire '81 WSW embodiment in his attempt to determine the scope of the inventions.

(c) Best Mode

The Examiner asserts that when “the disclosed best mode is a ‘unified system’, consideration of the entire monopoly (already enjoyed) is clearly more proper than a mere consideration of a portion of the monopoly already enjoyed.” (Office Action at 132.) Again, the Examiner has misconstrued the policy behind obviousness-type double patenting. The scope of the invention is determined by the claim language. The best mode disclosed in the specification as interpreted by the Examiner does not define the boundaries of the claims when determining double patenting of the obviousness-type. Examiner wrongly believes that “each already patented best mode embodiment 1)-3), necessarily requires the other two already patented best mode embodiments. . . .” (Office Action at 133.) Examiner has again improperly relied on the specification to interpret the scope of the invention while failing to analyze the pending claims on a limitation-by-limitation basis to demonstrate that no patentable distinctions exist between the pending claims and those in the issued Harvey patents.

In *In re Schneller*, 397 F.2d 350, 158 U.S.P.Q. 210 (C.C.P.A. 1968), the Schneller patent disclosed elements A, B, C, X, and Y as the best mode and claimed A, B, C, and X which covered other features incorporated in the claim because of the term “comprising”, thus effectively covering the combination A, B, C, X, and Y. The later filed application claimed elements A, B, C, and Y and elements A, B, C, X, and Y. Thus, making the new combination would merely exercise skill or ingenuity expected of a person with ordinary skill in the art because X and Y were both known in the art.

The court in *In re Schneller* noted the uniqueness of the factual circumstances surrounding the element composition of the application which involved the substitution of element X for element Y, rather than the addition or subtraction of an element from the patent’s claims.³⁰ The court went on to state that “[this] is not a case of an improvement

³⁰ 397 F.2d at 353-54.

or modification invented after filing . . . Hence it is not the usual ‘obviousness-type’ double patenting case.”³¹ Thus, the court limited the applicability of this holding. The Examiner has not offered any proof that *Schneller*’s use of the disclosed best mode may be properly applied to the facts of the instant application. More specifically, the instant case does not involve the substitution of one element (X) for another element (Y) where the rest of the claimed subject matter (ABC) is well known and where the two elements (X and Y) are also known in the art.

The Examiner erroneously relies on an alleged disclosed best mode as a ‘unified system’ as a basis for considering the entire monopoly and refers to pending claims as nothing more than “a mixing and matching of one or more of the three best mode embodiments that have already been patented”. (Office Action at 132-133.) While *In re Schneller* relied on a disclosed best mode of ABCXY in finding a non-statutory double patenting rejection, the Examiner’s use of a best mode to find all variations obvious is unwarranted. An allegation of an improper extension of a unified system monopoly cannot be supported without examining the scope of the claims. In *In re Schneller*, the court specifically cited and analyzed both the claims in the patent and the elements in the claims in the *Schneller* application. The court then clearly demonstrated how the claims in the patent read on the claims in the application to support the double patenting rejection. The Office Action fails to provide such an analysis.

(d) Means Plus Function

In interpreting “means plus function” language, the Federal Circuit held *In re Lonardo*, 119 F.3d 960, 43 U.S.P.Q.2d 1262 (Fed. Cir. 1997) that under 35 U.S.C. § 112, sixth paragraph³², correct interpretation of the means plus function element must be in light of the disclosed structure for implementing the function, and in a manner that is

³¹ *Id.*

³² See *In re Donaldson*, 16 F.3d 1189, 1193, 29 USPQ2d 1845, 1849 (Fed. Cir. 1994).

expressly recited in the claim.³³ The PTO must apply 35 U.S.C. §112, sixth paragraph, in appropriate cases, and give claims their broadest reasonable interpretation in light of and consistent with the written description of the invention in the application.³⁴

The Examiner has failed to properly interpret the “means plus function” language in making the obviousness-type double patenting rejections. Specifically, the Examiner has failed to construe the scope of the structures disclosed in the specification for the claimed means. Also, the Examiner has not established that the means disclosed in the specification are structurally equivalent to that embodied in the patents. Examiner’s analysis is lacking in the most basic respects. Thus, a *prima facie* case of obviousness-type double patenting has not been shown.

**(2) Establishing Variations between the Invention Claimed
and the Invention Defined in the Patent Claims**

Based on the proper identification of each of the inventions, *supra*, the Examiner then must identify the variation(s) between the inventions being claimed in the application and the invention as defined by the claims in the patent.

As discussed above, the Examiner has not properly identified the inventions in paragraph 29 or 30. In fact, the Examiner has failed to analyze and interpret the claims on a limitation-by-limitation basis to demonstrate that no patentable distinctions exist between the pending claims and those in the issued Harvey patents. Rather, in an attempt to address the variations between the inventions, the Examiner provides broad allegations that “the pending claims merely reflect an obvious variant ...” (Office Action at 131.) However, the Examiner has failed to specifically identify these variations. Such blanket

³³ *In re Lonardo*, 43 USPQ2d at 1267.

³⁴ *In re Donaldson*, 16 F.3d at 1194.

assertions do not fulfill the requirement of identifying variations between the invention claimed and the invention defined by the patent claims. as mandated by the M.P.E.P.

As to paragraph 30, the Examiner presents a weak attempt at establishing variations between the invention claimed and the invention defined in the patent claims. More specifically, the Examiner states that "[t]he differences are suggested by the art discussed within this action (see above; see below)." (Office Action at 135.) The Examiner erroneously believes that incorporating any differences merely **suggested** (and not necessarily explicitly stated) by any and all prior art discussed throughout the one hundred and forty seven (147) page Office Action is proper. The Examiner is required to identify the variations between the inventions being claimed and the invention as defined by the patent claims. Placing the burden on Applicants to sift through the Office Action to locate any and all discussions of the differences suggested, explicitly and/or implicitly, by the prior art is contrary to law. There is no statutory basis for Examiner's version of identifying variations between the sets of claims at issue.

Applicants provide Appendix B herewith, which identify Applicants' patentable subject matter of the instant claims over Applicants' patented claims. Due to the Examiner's failure to specify a proper and complete comparison to each of Applicants' pending claims to each of Applicants' patented claims, Applicants have provided an independent claim by independent claim comparison, specifying patentable subject matter, in the instant pending claim by underlining portions of claim language and summarizing any

(3) Variations Would Have Been Obvious to a Person of Ordinary Skill in the Art

The factual inquiries set forth in *Graham v. John Deere Co.*, 383 U.S. 1, 148 U.S.P.Q. 459 (1966) that establish a background for determining obviousness under 35 U.S.C. § 103 are employed when making an obviousness-type double patenting analysis.

However, the “patent principally underlying the double patenting rejection is not considered prior art.”³⁵ The factual inquiries are summarized as follows:

- (A) Determine the scope and content of the patent claim and the prior art relative to the claim in the application at issue;
- (B) Determine the differences between the scope and content of the patent claim and the prior art as determined in (A) and the claim in the application at issue;
- (C) Determine the level of ordinary skill in the pertinent art; and
- (D) Evaluate any objective indicia of nonobviousness.³⁶

Additionally, the Federal Circuit held in *Kaplan* that obviousness-type double patenting rejections must include clear evidence to establish why an alleged variation of an invention claimed in a prior patent would have been obvious.

[T]here must be some clear evidence to establish why the variation would have been obvious which can properly qualify as “prior art.” Even if obviousness of the variation is predicated on the level of skill in the art, prior art evidence is needed to show what the level of skill was.³⁷

Otherwise, if no clear prior art evidence establishes that the variation(s) in the application claims are obvious over the invention defined by the claims of the patent, one can assume that the characteristic of the claims including the variation(s),

appear that the invention covered by the later patent was a separate invention, distinctly different and independent from that covered by the first patent; in other words, it must be something substantially different from that comprehended in the first patent. It must consist in something

³⁵ *In re Longi*, 759 F.2d at 892, n.4 (citing *In re Braithwaite*, 379 F.2d 594, 600 n.4, 54 CCPA 1589, 154 USPQ 29 (CCPA 1967)).

³⁶ M.P.E.P. § 804 (II) B (1).

³⁷ *Id.* at 683.

more than a mere distinction of the breadth or scope of the claims of each patent.³⁸

As discussed above, the Examiner has failed to properly identify the inventions as claimed and has further failed to identify the variations as required for a proper obviousness-type double patenting rejection. The Examiner erroneously asserts that “since the pending claims merely reflect an obvious variant of the ‘81 disclosed WSW monopoly for which Applicants have long enjoyed a monopoly”, an obviousness-type double patenting rejection is therefore proper. (Office Action at 131.) Nonstatutory double patenting is intended to prevent prolongation of the patent term by prohibiting the extension of patent monopolies in successive patents. While the prohibition of extending patent monopolies is a policy concern, a statement of motivation for establishing obviousness under 35 U.S.C. § 103 is nevertheless lacking. Because Examiner has not provided any evidence that establishes that the variations are obvious over the invention as defined by the claims, the claims of the instant application may be assumed to be a separate and distinct invention.

Under paragraph 30, in an attempt to address the obviousness of the variations, the Examiner states that “[t]he provision of any such differences would have been obvious for the benefit of providing greater functionality to the user” (Office Action at 135.) The Examiner provides a single statement of motivation to address any differences without positively identifying the differences.

This statement lacks the proper motivation for establishing obviousness under 35 U.S.C. § 103 for at least the following reasons. First, “for the benefit of providing greater functionality to the user” does not answer the question of whether the differences would have been obvious to one of ordinary skill in the art. This attempt at providing motivation fails to take into consideration the level of ordinary skill at the time

³⁸ *Miller v. Eagle Mfg. Co.*, 151 U.S. at 198.

of the invention. To determine whether greater functionality provides adequate motivation, the Examiner should take into consideration (among other things) the level of ordinary skill in the art, as expressly provided in M.P.E.P § 804 (II)B(1) and *Graham v. John Deere Co.*³⁹ A proper motivation statement takes into consideration what would have been obvious to someone with ordinary skill in the art at the time of the invention. Without this determination, a modification cannot be deemed obvious for “greater functionality”. Examiner attempts to provide the level of ordinary skill in the art on pages 135-145. However, the Examiner nevertheless fails to provide a teaching as to how the differences would have been obvious. A variation may not be assumed to be obvious merely because greater functionality is alleged to be provided. The Examiner has failed to provide a proper statement of motivation.

Second, Examiner’s statement of motivation is overly broad. The statement of “greater functionality to the user” does not adequately provide a teaching to one of ordinary skill in the art. According to the Examiner’s reasoning, any and all differences between sets of claims, whether novel or not, will be considered obvious due to “greater functionality”. The Examiner’s version of motivation is improper and erroneous.

Third, while a variation provides “greater functionality”, it may also be considered novel and non-obvious. For example, while an improvement on a widget provides “greater functionality”, the improvement may just as well be novel and therefore merit patent protection. Non-obvious improvements provide “greater functionality” to the user. Likewise, a mere change in color may also provide greater functionality to the user. However, based on the level of ordinary skill in the art at the time of the invention, a mere color change may be considered to be an obvious variation. Because Examiner’s version of motivation may be construed in two dynamically different ways, the

³⁹ 383 U.S.1, 148 USPQ 459 (1966).

motivation statement of providing "greater functionality to the user", as applied to "any such differences" is clearly deficient.

5. Conclusion

The Examiner's basis for the double patenting rejections is inconsistent with the Patent Office Procedures found in the M.P.E.P. The Examiner has fatally misapplied and confused the established law of double patenting. The belief that if two claims in separate applications are supported by the same embodiment in the application's common specification as being a *prima facie* basis for obviousness-type double patenting rejections is not supported by the rules and procedures as set forth in the M.P.E.P. Furthermore, the Examiner has not cited any case law or any other authority, for that matter, for this erroneous basis.

To establish a proper obviousness-type double patenting rejection, the PTO must show that (1) the inventions claimed (2) are not patentably distinct and (3) are based on a *prima facie* showing of obviousness. According to § 804 of the M.P.E.P., any obviousness-type double patenting rejection should make clear the differences between the inventions defined by the conflicting claims; and the reasons why a person of ordinary skill in the art would conclude that the invention defined in the claim in issue is an obvious variation of the invention defined in a claim in the patent. As discussed above, the Examiner has not identified the claimed inventions; established variations; or shown that variations would have been obvious to a person of ordinary skill in the art.

Therefore, the Examiner has failed to properly establish a *prima facie* basis for a double patenting rejection of the obviousness type. Applicants respectfully request withdrawal of the rejection of all pending claims.

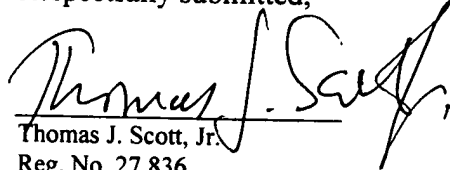

III. CONCLUSION

In accordance with the foregoing it is respectfully submitted that all outstanding objections and rejections have been overcome and/or rendered moot. Further, all pending claims are patentably distinguishable over the prior art of record, taken in any proper combination. Thus, there being no further outstanding objections or rejections, the application is submitted as being in a condition for allowance, which action is earnestly solicited.

If the Examiner has any remaining informalities to be addressed, it is believed that prosecution can be expedited by the Examiner contacting the undersigned attorney for a telephone interview to discuss resolution of such informalities.

Dependent Claim 65

wherein said interactive video apparatus includes a computer, said method further comprising the steps of:				See Fig. 6C.
organizing first information contained in said first discrete signal with second information contained in a second discrete signal in order to enable said interactive video apparatus to process at least one processor instruction which comprises said first information and said second information; and	Microcomputer, 205, see Fig. 7C.	... one or more processor/monitors and/or buffer/comparators that organize ... the information stream. In all cases, signals may convey information in discrete words, transmitted at separate times or in separate locations, ... TV signal decoder, 203, which is described more fully below, has capacity for ... converting the received information, as may be required, by means of input protocol techniques, ... into digital signals that ... control the operation of microcomputer, 205; ... But, in the preferred embodiment, the controller of the decoder that detects the SPAM signals of a combined medium transmission, ... and the controller that executes the information of said signals at the microcomputer ... are one and the same. ... Thus the preferred embodiment of controller, 39, is configured and preprogrammed not only to control the detecting, correcting, converting, and executing of controlled functions at decoder, 203, but also to input to and execute at microcomputer, 205, the information of any given	Microcomputer 205, see Fig. 6C. Column 7 lines 35-40. Column 2 line 64 to column 3 line 8. Column 19 lines 45-48.	Buffer/comparator, 8, organizes the data stream that it receives according to a pre-determined fashion that enables buffer/comparator, 8, among other things, to assemble signal units from signal words. (The term "signal unit" hereinafter means one complete signal instruction or information message unit. Examples of signal units are a unique code identifying a programming unit, or a unique purchase order number identifying the proper use of a programming unit, or a general instruction identifying whether a programming unit is to be retransmitted immediately or recorded for delayed transmission. The term "signal word" hereinafter means one full discrete appearance of a signal as embedded at one time in one location on a transmission. Examples of signal words are a string of one or more digital data bits encoded together on a single line of video or sequentially in audio. When the "Wall Street Week" transmission begins at 8:30 PM on a Friday evening, several instruction signals are identified by decoder, 203, and transferred to microcomputer, 205.

transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.			(e.g., Figs. 3A-C) to the receiver station of Fig. 6C.	instructs microcomputer, 205, to transmit the first overlay to TV set, 202, for as long as it receives the same instruction signal from processor, 204.
	Page 23 line 35 through Page 24 line 16	Subsequently, a second series of instructions is embedded and transmitted at said program originating studio. ... Microcomputer, 205, evaluates the initial signal word or words which instruct it to load at RAM ... and run ... a particular set of instructions that follows said word or words ... (Hereinafter, such a set of instructions that is loaded and run is called a "program instruction set.")	Column 19 lines 45-67.	When the "Wall Street Week" transmission begins at 8:30 PM on a Friday evening, several instruction signals are identified by decoder, 203, and transferred to microcomputer, 205. These signals instruct microcomputer, 205, to generate several graphic video overlays, ... At this point, an instruction signal is generated in the television studio originating the programming and is transmitted in the programming transmission. This signal is identified by decoder, 203, and transferred via processor, 204, to microcomputer, 205. This signal instructs microcomputer, 205, to transmit the first overlay to TV set, 202, for as long as it receives the same instruction signal from processor, 204.

Dependent Claim 76

receiving at least a portion of said first video image at said one of said first and said second transmitter station; and	Page 25 lines 28-31.	Then the host says, "Now as we turn to the graphs, here is what the Dow Jones Industrials did in the week just past," and a studio generated graphic is transmitted.	Column 19 lines 53-59.	Subsequently in the program, the host says, "Here is what the Dow Jones Industrials did is the past week," and a studio generated graphic....
	Page 20 line 26 to page 21 line 1.	Said WNET station is an intermediate transmission station for said program which actually originates at a remote television studio in Owings Mills, Maryland. (Hereinafter, a studio or station that originates the broadcast transmission of programming is called the "program originating studio.") From

	References	Language	References	Language
said locally generated video image,	through 7.	graphic image, and transmits another image such as the host's talking head. Simultaneously, the GRAPHICS OFF command causes microcomputer, 205, to cease overlaying the graphic information onto the received composite video and to commence transmitting the received composite video transmission unmodified.	Column 20 lines 4-7.	portfolio did." and the microcomputer, 205, ceases transmitting its own graphic to TV set, 202, and prepares to send the next locally generated graphic overlay upon instruction from the originating studio.
said method further comprising the steps of:	Page 25 lines 28-34.	Then the host says, "Now as we turn to the graphs, here is what the Dow Jones Industrials did in the week just past," and a studio generated graphic is transmitted. Fig. 1B shows the image of said graphic as it appears on the video screen of TV monitor, 202M. Then the host says, "And here is what your portfolio did."	Column 19 lines 54-60.	Subsequently in the program, the host says, "Here is what the Dow Jones Industrials did is the past week," and a studio generated graphic is pictured. The host then says, "Here is what the broader NASDAQ index did in the week past," and a studio generated graphic overlay is displayed on top of the first graphic. Then the host says, "And here is what your portfolio did."
outputting said audio at said interactive video apparatus before ceasing to display said locally generated video image.	<i>Please see the above citation with Page 27 lines 1 through 7.</i>	Then said studio ceases transmitting the graphic image, and transmits another image such as the host's talking head. Simultaneously, the GRAPHICS OFF command causes microcomputer, 205, to cease overlaying the graphic information onto the received composite video and to commence transmitting the received composite video transmission unmodified.	<i>Please see the above citation with column 19 lines 60-67</i>	At this point, an instruction signal is generated in the television studio originating the programming and is transmitted in the programming transmission. This signal is identified by decoder, 203, and transferred via processor, 204, to microcomputer, 205. This signal instructs microcomputer, 205, to transmit the first overlay to TV set, 202, for as long as it receives the same instruction signal from processor, 204.
Dependent Claim 92				
wherein said at least one control signal is effective at the remote intermediate transmitter	Page 434 line 34 to page 435 line 15.	Subsequently, executing said timing instructions causes said computer, 73, to execute said interconnect-and-encrypt-the-audio-of-WSW instructions.	Column 11 lines 44-65.	Controller/computer, 73, has means for communicating control information with matrix switch, 75, and video recorder/players, 76 and 78. If incoming

	References	Language	References	Language

station to control at least one of a plurality of selective transfer devices at different times.		Executing said last named instructions causes said computer, 73, to cause apparatus of said station to receive the transmission of the program originating studio of the "Wall Street Week" program; to input said transmission, via the matrix switch, 75, of said station, to particular apparatus, well known in the art, that encrypt the audio portion of said transmission and output the video and encrypted audio portions of said transmission in proper synchronization; to cause said apparatus to encrypt the information of said audio portion using a particular preprogrammed cipher algorithm C and cipher key Ca; and to transfer the output of said apparatus, via matrix switch, 75, to field distribution system, 93, via the particular modulator, 82, 86, or 90, of cable channel 13.		programming is meant for immediate transmission, controller/computer, 73, instructs matrix switch, 75, to configure its switches so as to transfer incoming programming to the proper output channel. For example, if controller/computer, 73, determines that programming incoming via receiver, 53, should be transmitted immediately to the field distribution system, 93, via cable channel modulator, 87, controller/computer, 73, instructs matrix switch, 75, to configure its switches so as to transfer programming transmissions inputted from TV receiver, 53, to the output that leads to modulator, 87. Similarly, if controller/computer, 73, determines that incoming programming should be recorded for delayed transmission, controller/computer, 73, selects a video recorder/player, 76 or 78, in a predetermined fashion, to record the incoming programming, instructs matrix switch, 75, to transfer the programming to the designated recorder/player, 76/78, and instructs the recorder/player, 76 or 78, to turn on and record the programming.

Independent Claim 93

A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and	Page 311 lines 10 through 16	... said program originating studio commences transmitting the programming information of said "Wall Street Week" program, thereby causing the apparatus of the station of Fig. 4 (and of other correctly regulated and connected stations) to commence functioning in the fashions described above in "One Combined Medium" and	See general example starting at column 19 lines 5 to column 20 line 7.

Dependent Claim 99

wherein said at least one first discrete signal designates a specific user input to process,	Page 24 lines 5-9.	Microcomputer, 205, evaluates the initial signal word or words which instruct it to load at RAM (from the input buffer to which decoder, 203, inputs) and run the information of a particular set of instructions that follows said word or words just as the information of a file named FILE.EXE,...	Specific user input is the Wall Street Week programming transmission and all associated control instructs transmitted therewith. Column 19 lines 42-44. As above, once the receiver station is enabled to receive the programming, then the overlay sequence per column 19 line 53 to column 20 line 2 commences.	Microcomputer, 205, is preprogrammed to respond in a predetermined fashion to instruction signals embedded in the "Wall Street Week" programming transmission. <i>See above.</i>
said method further comprising the step of generating output by processing said specific user input.	Page 26 line 9. Page 24 lines 14-27.	...the image shown in Fig. 1C which is the microcomputer generated graphic of the subscriber's own portfolio performance.... (Hereinafter, such a set of instructions that is loaded and run is called a "program instruction set.") In a fashion well known in the art, microcomputer, 205, ... executes said set as an assembled, machine language program in a fashion well known in the art. ... microcomputer, 205, calculates the performance of the subscriber's stock portfolio and constructs a graphic image of that performance at the installed graphics card.		

Dependent Claim 100

receiving said at least one subscriber datum; and	Page 21 lines 5-10.	At said subscriber station, microprocessor, 205, contains a conventional 5 1/4" floppy disk at a designated one of its disk drives that holds a data file recorded in a fashion well known in the art. Said file contains	Column 19 lines 35-37.	Each weekday, microcomputer, 205, receives, about 4:30 PM, by means of a digital information channel, all closing stock prices applicable that day
---	---------------------	---	------------------------	--

Claim Language	Support to instant specification filed June 6, 1995.		Support to Applicants' U.S. Pat. No. 4,690,490 filed November 3, 1981.	
	References	Language	References	Language

		information on the portfolio of financial instruments owned by the subscriber...		
passing said at least one subscriber datum to a storage device.	Page 24 lines 23-26.	...accessing the subscriber's contained portfolio data file for information in a fashion well known in the art, microcomputer, 205, calculates the performance of the subscriber's stock portfolio....	Column 19 lines 39-41.	It records those prices that relate to the stocks in its stored portfolio.

Dependent Claim 101

further comprising the step of communicating to a remote station data evidencing	Page 271 line 33 through page 272 line 1.	In examples #3, #4, and #5, the transmission of SPAM signal information causes signal processor, 200, to transfer signal record information by telephone to remote station computers.	Processor 200 of Fig. 6C has telephone connection 22 (See Fig. 1) whose functionality enables processor 200 to communicate signals externally, column 10 lines 4-8,	The controller, 20, also controls the automatic telephone dialing device, 24, which can automatically output the digital information on the digital recorder, 12, to a remote site through a telephone connection, 22.
at least one of (1) an availability, (2) a use, and (3) usage of at least one of (a) said at least one first discrete signal, (b) said at least one processor instruction, and (c) said video image.	Page 180 lines 1-4. Page 181 lines 1-5.	Then said process-monitor-info instructions cause onboard controller, 14A, to initiate a new monitor record that reflects the new "Wall Street Week" programming. Automatically, said instructions cause onboard controller. From the command meter-monitor segment of the 1st monitor information (#3), onboard controller, 14A, selects and records at particular signal record field locations at said record location the information that identifies the program unit of the particular "Wall Street Week" program...	column 15 lines 26-32, and column 18 lines 38-42.	Figure 5 illustrates methods for monitoring reception and operation which methods can be used to gather statistics on programming usage and associated uses of other data transmissions and equipment. Simultaneously, processor, 200, is also monitoring sequentially all other broadcast transmissions in the locality to gather further data on programming availability to record and transmit to a remote site.

Dependent Claim 102

communicating a	Page 312 lines 6-8.	...interrogate remote station apparatus,	Column 19 lines 35-39.	Each weekday, microcomputer, 205,
-----------------	---------------------	--	------------------------	-----------------------------------

----------------	------------	----------	--	------------	----------	--

Dependent Claim 161

wherein said one or more control signals are effective at said remote intermediate transmitter station to control one or more of a plurality of selective transfer devices.	Page 366 lines 19-20. Page 367 lines 2-9.	...at the scheduled time of the playing of Q, the station of Fig. 6 is transmitting via modulator, 83.... Receiving said message and mark causes computer, 73, to cause recorder, 76, to commence playing and to cause matrix switch, 75, to configure its switches so as to cease transferring programming inputted from distribution amplifier, 63, to modulator, 83, then to commence transferring the output of recorder, 76, to modulator, 83, which causes the transmission of unit Q to field distribution system, 93.	E.g., column 11 lines 44-58, shows how control information received at controller 73 via processor 71 (i.e., of Fig. 1) can control video recorder/players, 76 and 78 to play and store selected programming.	Controller/computer, 73, has means for communicating control information with matrix switch, 75, and video recorder/players, 76 and 78. If incoming programming is meant for immediate transmission, controller/computer, 73, instructs matrix switch, 75, to configure its switches so as to transfer incoming programming to the proper output channel. For example, if controller/computer, 73, determines that programming incoming via receiver, 53, should be transmitted immediately to the field distribution system, 93, via cable channel modulator, 87, controller/computer, 73, instructs matrix switch, 75, to configure its switches so as to transfer programming transmissions inputted from TV receiver, 53, to the output that leads to modulator, 87.
			Column 11 lines 38-44.	By comparing identification signals on the incoming programming with the programming schedule received earlier from local input, 74, and/or from a remote site via network, 98, controller/computer, 73, can determine when and on what channel or channels the head end facility should transmit the programming.
			Column 11 lines 50-57.	...if controller/computer, 73, determines that programming incoming via receiver, 53, should be transmitted immediately to the field distribution system, 93, via cable channel modulator, 87, controller/computer, 73, instructs matrix switch, 75, to configure its switches so as to transfer programming transmissions inputted

video graphic presentation.		the graphs, here is what the Dow Jones Industrials did in the week just past," and a studio generated graphic is transmitted.		
-----------------------------	--	---	--	--

Dependent Claim 170

wherein said audio describes information displayed in said video graphic presentation.	Page 25 lines 28-31.	Then the host says, "Now as we turn to the graphs, here is what the Dow Jones Industrials did in the week just past," and a studio generated graphic is transmitted.	Column 19 lines 53-56.	Subsequently in the program, the host says, "Here is what the Dow Jones Industrials did in the past week," and a studio generated graphic is pictured.
--	----------------------	--	------------------------	--

Independent Claim 171

A method of delivering a video graphic presentation at least one receiver station of a plurality of receiver stations, each of which (a) includes	Page 26 lines 8 through 11	TV monitor, 202M, then displays the image shown in Fig. 1C which is the microcomputer generated graphic of the subscriber's own portfolio performance overlaid on the studio generated graphic.	Generally see Fig. 6C, and column 19 line 5 to column 20 line 2.	
	Page 19 lines 6 through 7	Fig. 1 shows a video/computer combined medium subscriber station.		
	Page 21 lines 25 through 28	Other similarly configured and preprogrammed subscriber stations also tune to the transmission of said "Wall Street Week" program ...		
	Page 19 lines 7 through 9	... the station receives a conventional television broadcast transmission at television tuner, 215.		
a receiver,			E.g., cable converter box 201 of Fig. 6C.	
a signal detector,	Page 21 lines 14 through 16	Decoder, 203, is preprogrammed to detect digital information ...	E.g., Decoder 30 of processor 200, Fig. 1.	
a processor to execute at least one processor	Page 25 line 34 through Page 26 line 3	... an instruction signal is generated at said program originating studio, ... and	E.g., processor 205 of Fig. 6C.	

Claim Language	References	Language	References	Language
instruction, and		transmitted. Said signal is identified by decoder, 203; ... and executed by microcomputer, 205, ...		Support to Applicants' U.S. Pat. No. 4,690,490 filed November 3, 1981.
a video monitor that has a viewing screen,	Page 20 line 16	TV monitor, 202M, ...	E.g., TV 202, of Fig. 6C.	
(b) is adapted to detect the presence of one or more control signals, and	Page 22 lines 23 through 24 Page 21 line 35 through Page 22 line 5	Decoder, 203, detects the embedded instruction information, ... At said program originating studio, ... a ... series of control instructions is generated, embedded ... and transmitted	At signal processor 200 with decoder 30 from Fig. 1.	
(c) is programmed to process said at least one processor instruction,	Page 21 lines 20 through 24	Microcomputer, 205, is preprogrammed ... to respond... to instruction signals embedded in the "Wall Street Week" programming transmission.	Column 19 lines 42-44.	Microcomputer, 205, is preprogrammed to respond in a predetermined fashion to instruction signals embedded in the "Wall Street Week" programming transmission.
wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion	Page 26 lines 4 through 10	Said signal instructs microcomputer, 205, ... to overlay the graphic information in its graphics card onto the received composite video information and transmit the combined information to TV monitor, 202M. TV monitor, 202M, then displays the image shown in Fig. 1C which is the microcomputer generated graphic of the subscriber's own portfolio performance overlaid on ...	Column 19 lines 60-67.	At this point, an instruction signal is generated in the television studio originating the programming and is transmitted in the programming transmission. This signal is identified by decoder, 203, and transferred via processor, 204, to microcomputer, 205. This signal instructs microcomputer, 205, to transmit the first overlay to TV set, 202, for as long as it receives the same instruction signal from processor, 204.
of a second completed full-screen video graphic image to said video monitor,				
wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor	Page 26 lines 8 through 11	TV monitor, 202M, then displays the image shown in Fig. 1C which is the microcomputer generated graphic of the subscriber's own portfolio	Column 19 line 67 to column 20 line 2.	The viewer then sees a microcomputer generated graphic of his own stocks' performance overlay the studio generated graphic.

Claim Language	Support to instant specification filed June 6, 1995. References	Language	Support to Applicants' U.S. Pat. No. 4,690,490 filed November 3, 1981. References	Language
and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor,	Page 25 lines 31 through 33	performance overlaid on the studio generated graphic.	Column 19 lines 54-56.	Subsequently in the program, the host says, "Here is what the Dow Jones Industrials did is the past week," and a studio generated graphic is pictured.
and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:	Page 26 lines 4 through 10	TV monitor, 202M, then displays the image shown in Fig. 1C which is the microcomputer generated graphic of the subscriber's own portfolio performance overlaid on the studio generated graphic.	Column 19 line 67 to column 20 line 2.	<i>See above.</i>
receiving at a transmitter station	Page 21 line 35 through Page 22 line 5	At said program originating studio, ... a first ... is generated, embedded sequentially on said line or lines ... word ...	Column 11 lines 3-5, and, column 19 lines 60-63.	Signal processor, 71, has means, described above, to identify and separate the instruction and information signals from their associated programming and pass them, At this point, an instruction signal is generated in the television studio originating the programming and is transmitted in the programming transmission.
at least one discrete signal that contains only	Page 14 lines 22 through 25	In all cases, signals may convey information in discrete words,	Column 7 lines 36-39.	Buffer/comparator, 8, organizes the data stream that it receives according to a pre-

APPENDIX B

**PATENTABLE SUBJECT MATTER OF
INSTANT CLAIMS OVER
APPLICANTS' PATENTED CLAIMS**

The following charts provide a claim by claim comparison of each of Applicants' instant independent claims⁴⁰ to each of Applicant's independent patented⁴¹ claims. The Office Action stated in paragraphs 29 & 30 that claims 56-181 are rejected under the judicially created doctrine of obviousness-type double patenting over any single claim or combination of claims of every claim of Applicants' six issued patents, (see footnote 41). However, the Office Action only compared claim 1 of U.S. Pat. No. 4,496,490 to each of Applicants' instant independent claims. There was no other analysis to any other of Applicants' patented claims with those of the instant application.

Applicants provide a complete analysis in Appendix B to show that the instant independent claims are patentably distinct from the patented independent claims. Appendix B is subdivided into 107 parts comparing the instant 18 independent claims to each independent patented claims (107 in total).

For the Examiner's convenience only, Applicants have underlined portions in the left columns of the instant 18 independent claims to designate the clearest and most succinct portions of the claim language that Applicants believe are patentably distinct from the patented independent claims in the right columns. Applicants assert that any lack of underlining in the instant independent claims in no way indicates these portions are common to the subject matter of the patented claims.

Below each claim comparison table are further explanations of how the claims are patentable distinct from each other, e.g., all of the instant independent claims are method claims whereas many of the patented claims are apparatus claims; additionally, there are distinctions between the general operating scope of the claims, i.e., one claim may deal with method of operation solely at a receiver station, whereas the other claim may deal with additional methods of operation at an origination station and/or a transmitter station.

⁴⁰ Independent claims 56, 75, 80, 84, 93, 110, 116, 123, 142, 143, 152, 157, 162, 167, 171, 175, 177 & 179, totaling 17 claims.

⁴¹ Applicants' issued U.S. Pat. Nos. 4,694,490, 4,704,725, 4,965,825, 5,109,414, 5,233,654 & 5,335,277.

Finally, at the end of each comparison is a paragraph that summarizes the certain portions of the instant claim language that Applicants believe to be patentably distinct over both the patented claims and the prior art of record.

The following is a summary of each of Applicants' patented independent claims:

U.S. Pat. No. 4,690,490

Independent Claims: 1, 4, 7, & 9.

U.S. Pat. No. 4,704,725

Independent Claims: 1 & 3.

U.S. Pat. No. 4,965,825

Independent Claims: 1-5, 14, 20, 24 & 25.

U.S. Pat. No. 5,109,414

Independent Claims: 1-19, 21-26.

U.S. Pat. No. 5,233,654

Independent Claims: 1, 6, 7, 10, 13, 16, 21, 32-34, 37, 38, 59, 63 & 67.

U.S. Pat. No. 5,335,277

Independent Claims: 1-8, 10-35, 38-53, 55 & 56.

Application Claim 56	U.S. Pat. No. 4,694,490, Claim 1
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus</u> in order to present said locally generated image with said image from said remote video source; and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Application Claim 75	U.S. Pat. No. 4,694,490, Claim 1
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers</p>

<p>containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p><u>transferring said downloadable processor instructions to a transmitter;</u></p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p><u>transferring said at least one control signal to said transmitter; and</u></p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	--

Application Claim 80	U.S. Pat. No. 4,694,490, Claim 1
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p><u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said</u></p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p>

<p>instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 84	U.S. Pat. No. 4,694,490, Claim 1
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of: <u>receiving video at a transmitter station;</u> delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals,</u> and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; <u>transferring said first discrete signal to said transmitter; and</u> transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of: transmitting a video signal containing a television program signal to said receivers, transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed, receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations, detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and causing said last named computers to generate and transmit their overlay signals to their associated</p>

	television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.
--	--

Application Claim 93	U.S. Pat. No. 4,694,490, Claim 1
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at least one information transmission at said receiver station, <u>said at least one information transmission containing at least one first discrete signal</u> and at least one control signal;</p> <p style="padding-left: 20px;"><u>detecting said at least one first discrete signal</u> and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 20px;"><u>passing said detected at least one first discrete signal</u> and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal</u>;</p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing</u>;</p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;">generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</p> <p style="padding-left: 20px;">outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p style="padding-left: 20px;">transmitting a video signal containing a television program signal to said receivers,</p> <p style="padding-left: 20px;">transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p style="padding-left: 20px;">receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p style="padding-left: 20px;">detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p style="padding-left: 20px;">causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Application Claim 110	U.S. Pat. No. 4,694,490, Claim 1
110. A method of outputting a video presentation	1. A method of communicating television program

<p>at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal</u>, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</p> <p><u>transferring said at least said first discrete signal to at least one transmitter;</u></p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p><u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	--

Application Claim 116	U.S. Pat. No. 4,694,490, Claim 1
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination</u></p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p>

<p><u>transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p><u>transferring said at least one control signal to said at least one origination transmitter before a specific time;</u></p> <p>and</p> <p><u>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</u></p>	<p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 123	U.S. Pat. No. 4,694,490, Claim 1
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the</p>

<p><u>transferring said at least one instruct signal to at least one transmitter;</u> <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u></p>	<p>video receivers of selected ones of said plurality of receiver stations, detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	---

Application Claim 142	U.S. Pat. No. 4,694,490, Claim 1
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, <u>said information transmission containing at least a first discrete signal and at least one control signal;</u> detecting said at least a first discrete signal and said at least one control signal in said information transmission; <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of: transmitting a video signal containing a television program signal to said receivers, transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed, receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations, detecting the presence of said instruct-to-overlay</p>

<p>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</p> <p>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</p>	<p>signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	--

Application Claim 143	U.S. Pat. No. 4,694,490, Claim 1
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p>outputting at least a portion of said video presentation based on said generated signal.</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each</p>

	display specific to a specific user.
--	--------------------------------------

Application Claim 152	U.S. Pat. No. 4,694,490, Claim 1
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</p> <p><u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Application Claim 157	U.S. Pat. No. 4,694,490, Claim 1
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers,</p>

<p>comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p>and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 162	U.S. Pat. No. 4,694,490, Claim 1
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p>receiving said at least said first of said plurality of</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user</p>

<p>discrete signals at said transmitter station, <u>wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code</u>, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	--

Application Claim 167	U.S. Pat. No. 4,694,490, Claim 1
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal</u>;</p> <p>responding to at least one processor instruction at</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling</p>

<p>said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	---

Application Claim 171	U.S. Pat. No. 4,694,490, Claim 1
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p>receiving at a transmitter station <u>at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the</p>

<p>receiving said one or more control signals at said transmitter station, <u>wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal</u>, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	--

Application Claim 175	U.S. Pat. No. 4,694,490, Claim 1
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected</p>

<p>full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image;</u> and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 4,694,490, Claim 1
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction</u> that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p>

<p>second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	---

Application Claim 179	U.S. Pat. No. 4,694,490, Claim 1
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying said second completed full-screen video</p>	<p>1. A method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, comprising the steps of:</p> <p>transmitting a video signal containing a television program signal to said receivers,</p> <p>transmitting an instruct-to-overlay signal to said receiver stations at a time when the corresponding overlay is not being displayed,</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations and coupling said instruct-to-overlay signal to the computers associated with the video receivers of said selected stations, and</p> <p>causing said last named computers to generate and transmit their overlay signals to their associated television receivers in response to said instruct-to-</p>

graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,
wherein said method delivers said video graphic presentation.

overlay signal, thereby to present a display at the selected receiver stations including the television program material and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.

Application Claim 56	U.S. Pat. No. 4,694,490, Claim 4
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus</u>, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations in an operating environment of a transmitter station only.

Application Claim 75	U.S. Pat. No. 4,694,490, Claim 4
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being</p>

<p>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, <u>wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions</u> and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>
---	--

Application Claim 80	U.S. Pat. No. 4,694,490, Claim 4
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of</u> generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 84	U.S. Pat. No. 4,694,490, Claim 4
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, <u>wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals</u>, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <ul style="list-style-type: none"> transmitting a video signal containing a television program signal to said receiver stations, and transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.

Application Claim 93	U.S. Pat. No. 4,694,490, Claim 4
<p>93. <u>A method of outputting a video presentation at a receiver station</u>, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; <u>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</u> passing said detected at least one first discrete signal and said detected at least one control signal to at least 	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <ul style="list-style-type: none"> transmitting a video signal containing a television

<p>one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</p>	<p>program signal to said receiver stations, and transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 110	U.S. Pat. No. 4,694,490, Claim 4
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal,</u> said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data; transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one</u></p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of transmitting a video signal containing a television program signal to said receiver stations, and transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a</p>

<p><u>control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>specific user.</p>
---	-----------------------

Application Claim 116	U.S. Pat. No. 4,694,490, Claim 4
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, <u>wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p><u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u></p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 123	U.S. Pat. No. 4,694,490, Claim 4
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

Application Claim 142	U.S. Pat. No. 4,694,490, Claim 4
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including</u></p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations</p>

<p>a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</p> <p>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</p>	<p>each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>
--	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations in an operating environment of a transmitter station only.

Application Claim 143	U.S. Pat. No. 4,694,490, Claim 4
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p>responding, at said processor, to processor instructions comprising said organized information,</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being</p>

<p>based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>
---	--

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 152	U.S. Pat. No. 4,694,490, Claim 4
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

downloadable processor instructions and said one or more control signals.	
---	--

Application Claim 157	U.S. Pat. No. 4,694,490, Claim 4
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p>and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 162	U.S. Pat. No. 4,694,490, Claim 4
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of</u></p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps</p>

<p><u>discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>of transmitting a video signal containing a television program signal to said receiver stations, and transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>
--	--

Application Claim 167	U.S. Pat. No. 4,694,490, Claim 4
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and displaying, at said video monitor, said second</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of transmitting a video signal containing a television program signal to said receiver stations, and transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

<p>completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 171	U.S. Pat. No. 4,694,490, Claim 4
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor</u></p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

<p><u>instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal</u>, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	
--	--

Application Claim 175	U.S. Pat. No. 4,694,490, Claim 4
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said</u></p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

<p><u>second completed full-screen video graphic image contains at least one graphic image:</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 177	U.S. Pat. No. 4,694,490, Claim 4
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen</u></p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

<p><u>video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	
--	--

Application Claim 179	U.S. Pat. No. 4,694,490, Claim 4
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said</p>	<p>4. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay control signals transmitted to their associated receivers, each of said computers being programmed to accommodate a unique user application, the steps of</p> <p>transmitting a video signal containing a television program signal to said receiver stations, and</p> <p>transmitting an instruct-to-overlay signal at a time when the corresponding overlay is not being displayed to thereby cause selected ones of said computers to generate and transmit their overlay signals to their associated television receiver to present a combined display consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display unique to a specific user.</p>

second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image, wherein said method delivers said video graphic presentation.	
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations in an operating environment of a transmitter station only.

Application Claim 56	U.S. Pat. No. 4,694,490, Claim 7
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Application Claim 75	U.S. Pat. No. 4,694,490, Claim 7
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote</u></p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the</p>

<p>transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, <u>wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 4,694,490, Claim 7
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p>

<p>of said video presentation to be displayed in conjunction with said video; <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal;</u> and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations, detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 4,694,490, Claim 7
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of: receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals,</u> and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; transferring said first discrete signal to said</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct to-overlay signal are transmitted to said receiver stations, the steps of receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations, detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the</p>

transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.	computers at said selected receiver stations, and causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.
---	--

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 4,694,490, Claim 7
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</p> <p>outputting said video presentation to a user, said video presentation containing, firstly, said video</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays</p>

image and, secondly, said generated image to replace said only said portion of said video image.	displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.
--	---

Application Claim 110	U.S. Pat. No. 4,694,490, Claim 7
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 4,694,490, Claim 7
116. A method of delivering a video presentation	7. In a method of communicating television

<p>at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p><u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u></p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 4,694,490, Claim 7
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay</p>

<p>and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 142	U.S. Pat. No. 4,694,490, Claim 7
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said</p>

<p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</p> <p>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</p>	<p>program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	--

Application Claim 143	U.S. Pat. No. 4,694,490, Claim 7
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p>responding, at said processor, <u>to processor instructions comprising said organized information,</u> based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p>

outputting at least a portion of said video presentation based on said generated signal.	<p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	---

Application Claim 152	U.S. Pat. No. 4,694,490, Claim 7
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations</p>

transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.	being different, with each display specific to a specific user.
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 4,694,490, Claim 7
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p>and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 4,694,490, Claim 7
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p style="padding-left: 40px;">receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p style="padding-left: 40px;">detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p style="padding-left: 40px;">causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 4,694,490, Claim 7
167. A method of outputting a video graphic	7. In a method of communicating television

<p>presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	---

Application Claim 171	U.S. Pat. No. 4,694,490, Claim 7
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said</p>

instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,

detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and

causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 175	U.S. Pat. No. 4,694,490, Claim 7
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 4,694,490, Claim 7
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor,</u> said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <p>receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations,</p> <p>detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and</p> <p>causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 179	U.S. Pat. No. 4,694,490, Claim 7
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image, wherein said method delivers said video graphic presentation. 	<p>7. In a method of communicating television program material to a multiplicity of receiver stations each of which includes a television receiver and computer, the computers being adapted to generate and transmit overlay video signals, to their associated television receivers, said overlay signals causing the display of user specific information related to said program material, and with at least some of said computers being programmed to process overlay modification control signals so as to modify the overlay video signals transmitted to their associated receivers, each of said computers being programmed to accommodate a specific user application, and wherein a video signal containing a television program signal and an instruct-to-overlay signal are transmitted to said receiver stations, the steps of</p> <ul style="list-style-type: none"> receiving said video signal at a plurality of receiver stations and displaying said program material on the video receivers of selected ones of said plurality of receiver stations, detecting the presence of said instruct-to-overlay signal at said selected receiver stations at a time when the corresponding overlay is not being displayed, and coupling said instruct-to-overlay signal to the computers at said selected receiver stations, and causing the computers at said selected receiver stations to generate and transmit their overlay video signals to their associated television receivers in response to said instruct-to-overlay signal, thereby to present a combined display at the selected receiver stations consisting of the television program and the related computer generated overlay, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.

Application Claim 56	U.S. Pat. No. 4,694,490, Claim 9
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 4,694,490, Claim 9
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

<p>receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 4,694,490, Claim 9
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video; <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal;</u> and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 4,694,490, Claim 9
<p>84. <u>A method</u> of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals,</u> and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 4,694,490, Claim 9
<p>93. <u>A method</u> of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; 	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for</p>

<p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</p> <p>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</p>	<p>generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 4,694,490, Claim 9
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target</u></p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

<p>processor to process data; transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 4,694,490, Claim 9
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

transmitter said first discrete signal and said at least one control signal.	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 4,694,490, Claim 9
<p>123. <u>A method</u> of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 4,694,490, Claim 9
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; generating only a portion of said video image based on said step of responding to said at least one processor instruction; and outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image. 	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 4,694,490, Claim 9
<p>143. A method of outputting a video presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least 	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally</p>

<p>one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	---

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 4,694,490, Claim 9
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said</u></p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

<p><u>downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 4,694,490, Claim 9
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p>and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 4,694,490, Claim 9
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations elements of an apparatus.

Application Claim 167	U.S. Pat. No. 4,694,490, Claim 9
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said</p>

<p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 4,694,490, Claim 9
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image,</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific</p>

<p>wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>user.</p>
--	--------------

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 4,694,490, Claim 9
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for</p>

<p>completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image,</u> said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image;</u> and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 4,694,490, Claim 9
177. <u>A method</u> of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor	9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver,

<p>that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor</u>, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
---	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 4,694,490, Claim 9
<p>179. <u>A method</u> of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video</p>	<p>9. Television signal processor means, comprising carrier transmission receiving means, means for demodulating the output of said receiving means to detect a video program signal, means normally coupling said video signal to a television receiver, decoder means for determining the presence or absence of an embedded instruct-to-overlay signal in said video signal at a time when the corresponding</p>

<p>monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>overlay is not being displayed, computer means for generating and transmitting video overlay signals, said overlay signals causing the display of user specific information related to said program material, and means connected to said computer means and responsive to said decoder means when the presence of said embedded signal is detected for coupling said overlay signals to said television receiver, the overlays displayed at a multiplicity of said receiver stations being different, with each display specific to a specific user.</p>
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 4,704,725, Claim 1
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</p> <p>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 75	U.S. Pat. No. 4,704,725, Claim 1
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u> said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an</p>

<p>processor instructions, <u>wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 80	U.S. Pat. No. 4,704,725, Claim 1
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at</p>

	a multiplicity of said output devices being different, with each output signal specific to a specific user.
--	---

Application Claim 84	U.S. Pat. No. 4,704,725, Claim 1
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application, transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Application Claim 93	U.S. Pat. No. 4,704,725, Claim 1
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; 	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-process signal to said computers to cause each of said computers to process

<p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 110	U.S. Pat. No. 4,704,725, Claim 1
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said</u></p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output</p>

<p><u>information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	--

Application Claim 116	U.S. Pat. No. 4,704,725, Claim 1
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p><u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u></p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 123	U.S. Pat. No. 4,704,725, Claim 1
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being</p>

<p>the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p style="padding-left: 20px;">transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p style="padding-left: 20px;">transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p style="padding-left: 20px;">transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p style="padding-left: 20px;">detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p style="padding-left: 20px;">causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 142	U.S. Pat. No. 4,704,725, Claim 1
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said</p>

<p>at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 143	U.S. Pat. No. 4,704,725, Claim 1
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p>responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p><u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output</p>

	<p>devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 152	U.S. Pat. No. 4,704,725, Claim 1
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 20px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 20px;">receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image</u>;</p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p style="padding-left: 20px;">transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p style="padding-left: 20px;">transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an... output device,</p> <p style="padding-left: 20px;">detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p style="padding-left: 20px;">causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 157	U.S. Pat. No. 4,704,725, Claim 1
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which</p>

<p>stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p>and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 162	U.S. Pat. No. 4,704,725, Claim 1
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said</u></p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said</p>

<p><u>code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>instruct-to-output signal to the computers associated with said selected stations, and causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 167	U.S. Pat. No. 4,704,725, Claim 1
<p>167. A method of outputting a video graphic presentation at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-</u></p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application, transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

<p><u>screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	
---	--

Application Claim 171	U.S. Pat. No. 4,704,725, Claim 1
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image,</u> wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

<p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	
--	--

Application Claim 175	U.S. Pat. No. 4,704,725, Claim 1
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p>transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p>causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

<p>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	
--	--

Application Claim 177	U.S. Pat. No. 4,704,725, Claim 1
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p> receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p> delivering said received first completed full-screen video graphic image to a transmitter;</p> <p> <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p> transferring said one or more instruct signals to said transmitter; and</p> <p> transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p> wherein said method delivers said video graphic presentation.</p>	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p> transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application,</p> <p> transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p> detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and</p> <p> causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 179	U.S. Pat. No. 4,704,725, Claim 1
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>1. A method of communicating data to a multiplicity of receiver stations, each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-process signal to said computers to cause each of said computers to process data in accordance with its associated special user application, transmitting an instruct-to-output signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-output signal at selected receiver stations and coupling said instruct-to-output signal to the computers associated with said selected stations, and causing said last named computers simultaneously to output their user specific signals to their associated output devices in response to said instruct-to-output signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Application Claim 56	U.S. Pat. No. 4,704,725, Claim 3
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having <u>a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 75	U.S. Pat. No. 4,704,725, Claim 3
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 80	U.S. Pat. No. 4,704,725, Claim 3
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 84	U.S. Pat. No. 4,704,725, Claim 3
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes</p>

<p>stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises <u>information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.
---	---

Application Claim 93	U.S. Pat. No. 4,704,725, Claim 3
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> 	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and

<p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image</u> by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	--

Application Claim 110	U.S. Pat. No. 4,704,725, Claim 3
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 116	U.S. Pat. No. 4,704,725, Claim 3
116. A method of delivering a video presentation	3. A method of communicating data to a

<p>at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 123	U.S. Pat. No. 4,704,725, Claim 3
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said</p>

<p><u>a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 142	U.S. Pat. No. 4,704,725, Claim 3
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and</p>

<p><u>information from said step of organizing:</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 143	U.S. Pat. No. 4,704,725, Claim 3
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 152	U.S. Pat. No. 4,704,725, Claim 3
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to <u>process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said</p>

<p><u>image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 157	U.S. Pat. No. 4,704,725, Claim 3
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p>

control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.	causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.
--	---

Application Claim 162	U.S. Pat. No. 4,704,725, Claim 3
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 167	U.S. Pat. No. 4,704,725, Claim 3
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said</p>

<p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 171	U.S. Pat. No. 4,704,725, Claim 3
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit</p>

<p><u>contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image,</u> wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic presentation.</p>	<p>signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p style="padding-left: 20px;">causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 175	U.S. Pat. No. 4,704,725, Claim 3
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p style="padding-left: 20px;">transmitting an instruct-to-transmit signal to said</p>

<p>displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>computers at a time when the corresponding user specific information is not being transmitted to an output device,</p> <p>detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 177	U.S. Pat. No. 4,704,725, Claim 3
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at</p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user</p>

<p>said video monitor; delivering said received first completed full-screen video graphic image to a transmitter; <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	<p>specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 179	U.S. Pat. No. 4,704,725, Claim 3
<p>179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal</u></p>	<p>3. A method of communicating data to a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify the user specific signals transmitted to their associated output devices, each of said computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-transmit signal to said computers at a time when the corresponding user specific information is not being transmitted to an output device, detecting the presence of said instruct-to-transmit signal at selected receiver stations and coupling said instruct-to-transmit signal to the computers associated with said selected stations, and causing said last named computers to generate and transmit their user specific signals to their associated</p>

<p><u>based on at least one control signal:</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>output devices in response to said instruct-to-transmit signal, thereby to transmit to the selected output devices an output signal comprising said data and said related user specific signals, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 1
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 1
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 1
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal;</u> and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 1
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 1
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image,</u> said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 1
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 1
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 1
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> <u>transferring said at least one instruct signal to at least one transmitter;</u> <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p><u>be effective at said at least one of said plurality of receiver stations; and</u> transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 1
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 1
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 1
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p>instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein <u>said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 1
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of: <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 1
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 1
<p>167. <u>A method of outputting a video graphic presentation at a receiver station</u> including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
---	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 1
171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u>	1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 1
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 1
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 1
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>1. In a signal processor system, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and removing it from said information transmission; first control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor system; second control means activated by said detected signal to monitor the performance and/or output of said first control means; a recorder means for receiving and recording data collected by said monitor means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 2
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 2
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 2
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 2
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 2
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image,</u> said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 2
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 2
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 2
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> <u>transferring said at least one instruct signal to at least one transmitter;</u> <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p><u>be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 2
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 2
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 2
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>information recorded thereon to a remote site.</p>
--	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 2
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 2
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 2
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 2
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 2
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 2
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 2
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>2. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for detecting an embedded signal in the information transmission and for removing said signal from said information transmission; control means responsive to said detected signal to activate and/or deactivate equipment external to said signal processor; monitor means activated by said detected signal to monitor the performance and/or output of said external equipment; a recorder means for receiving and recording data collected by said monitor means; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within a predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of an elements of an apparatus.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 3
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 3
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 3
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 3
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 3
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 3
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time</p>

<p>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 3
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at</p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

<p>least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 3
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

<p><u>be effective at said at least one of said plurality of receiver stations; and</u> transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 3
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 3
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 3
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>thereon to a remote site.</p>
--	----------------------------------

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 3
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 3
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p><u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 3
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 3
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 3
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 3
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 3
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>3. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; recorder means for receiving and recording the presence or absence of said detected signal; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder means to transmit the information recorded thereon to a remote site.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 4
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 4
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>
--	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 4
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	location in succeeding information transmissions examined for embedded signals.
---	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 4
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and <u>said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 4
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 4
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within</p>

<p>contained in a second discrete signal, <u>said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation</u>, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 4
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter</u>, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</p> <p>receiving at least one control signal which at said</p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; <u>transferring said at least one control signal to said at least one origination transmitter</u> before a specific time; and <u>transmitting from said at least origination transmitter</u> said first discrete signal and said at least one control signal.	examined for embedded signals.
--	--------------------------------

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 4
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

<p>receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 4
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image</u>, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 4
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <p><u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u></p> <p><u>passing said received video image to an output device for delivery to a user;</u></p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</p> <p>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p><u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 4
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image</u>;</p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 4
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control</p>

receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.	means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.
--	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 4
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of: <u>receiving a video image at a transmitter station; delivering said video image to a transmitter;</u> receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and <u>wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates

claim 162 over the patented claim's recitations in an operating environment of a receiver •transmitter station only.

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 4
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 4
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</p> <p>transferring said at least one discrete signal to a transmitter;</p> <p>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, <u>said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least</p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

<p>one discrete signal and said one or more control signals, <u>wherein said method delivers said video graphic presentation.</u></p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 4
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u> <u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-</p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

<p>screen video graphic image; and <u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 4
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u> <u>delivering said received first completed full-screen video graphic image to a transmitter;</u> <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> <u>transferring said one or more instruct signals to said transmitter; and</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,
wherein said method delivers said video graphic presentation.

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 4
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p>	<p>4. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in said information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct received said carrier transmission to said demodulating means and said detector means; control means for instructing said recorder to direct information recorded thereon to a remote site; control means responsive to some of said detected signals in said data stream to activate and/or deactivate equipment external to said signal processor; and control means responsive to some other of said detected signals in said data stream to alter the location in succeeding information transmissions examined for embedded signals.</p>

<u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 5
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 5
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u></p> <p>said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 5
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 5
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and <u>said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 5
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image,</u> said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal; passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 5
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, <u>said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the</p>

<p>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data; transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 5
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; <u>transferring said at least one control signal to said at</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p><u>least one origination transmitter before a specific time;</u> and <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u></p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 5
<p>123. <u>A method of delivering a video presentation</u> <u>at at least one of a plurality of receiver stations</u> each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video</u> <u>presentation includes a first image which is received at</u> <u>one of said plurality of receiver stations from a first</u> <u>remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving at at least one of said first remote</u> <u>transmitter station and a second remote transmitter</u> <u>station at least one instruct signal which is effective at</u> <u>a particular receiver station of said plurality of receiver</u> <u>stations to generate locally and output said second</u> <u>image of said video presentation for delivery in</u> <u>conjunction with said first image;</u></p> <p style="padding-left: 40px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 40px;">receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 5
<p><u>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 5
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 5
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means</p>

<p>instructions to a transmitter;</p> <p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 5
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 5
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and <u>wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 5
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 5
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 5
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 5
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 5
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>5. In a signal processor, carrier transmission receiving means; means for demodulating said carrier transmission to detect an information transmission thereon; detector means for determining the presence or absence of an embedded signal in the information transmission within a predetermined time interval and for detecting said signal and removing it from said information transmission; buffer means for organizing said detected signals with detected signals from other detector means into a data stream; recorder means for receiving and recording said data stream; control means for instructing said carrier receiving means to receive the appropriate carrier transmission within said predetermined time interval and to direct said received carrier transmission to said demodulating means and said detector means; control means for instructing said detector means to detect the presence or absence of said embedded signal within said predetermined time interval; and control means for instructing said recorder to direct information recorded thereon to a remote site.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 14
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 14
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor</u></p>	<p>14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

<p>instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 14
<p>80. A method of <u>delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 14
<p>84. A method of <u>delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>14. A method of processing signals including:</p> <p>(a) the step of receiving a carrier transmission;</p> <p>(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p>(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p>(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;</p> <p>(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p>(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 14
<p>93. A method of <u>outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p>	<p>14. A method of processing signals including:</p> <p>(a) the step of receiving a carrier transmission;</p> <p>(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p>(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p>(d) the step of passing said embedded signals to a device or devices to be controlled based on</p>

<p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>instructions identified within said embedded signals;</p> <p>(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p>(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>
---	--

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 14
<p>110. A method of <u>outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p>	<p>14. A method of processing signals including:</p> <p>(a) the step of receiving a carrier transmission;</p> <p>(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p>(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p>(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;</p> <p>(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p>(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

<p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 14
<p>116. A method of <u>delivering a video presentation</u> at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 20px;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 20px;">transmitting from said at least origination transmitter said first discrete signal and said at least</p>	<p>14. A method of processing signals including:</p> <p style="padding-left: 20px;">(a) the step of receiving a carrier transmission;</p> <p style="padding-left: 20px;">(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p style="padding-left: 20px;">(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p style="padding-left: 20px;">(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;</p> <p style="padding-left: 20px;">(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p style="padding-left: 20px;">(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

one control signal.	
---------------------	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 14
<p>123. A method of <u>delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p style="padding-left: 20px;">transferring said at least one first discrete signal and said control signal to said at least one transmitter, said</p>	<p>14. A method of processing signals including:</p> <p style="padding-left: 20px;">(a) the step of receiving a carrier transmission;</p> <p style="padding-left: 20px;">(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p style="padding-left: 20px;">(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p style="padding-left: 20px;">(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;</p> <p style="padding-left: 20px;">(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p style="padding-left: 20px;">(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

<p>at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 14
<p>142. A method of <u>outputting a video presentation</u> at a receiver station, <u>said video presentation including a video image</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>14. A method of processing signals including:</p> <p style="padding-left: 20px;">(a) the step of receiving a carrier transmission;</p> <p style="padding-left: 20px;">(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p style="padding-left: 20px;">(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p style="padding-left: 20px;">(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;</p> <p style="padding-left: 20px;">(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p style="padding-left: 20px;">(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 14
<p>143. A method of <u>outputting a video presentation</u> at a receiver station including:</p> <p style="padding-left: 20px;"><u>receiving a transmission from a remote station, said transmission containing a video image and at least</u></p>	<p>14. A method of processing signals including:</p> <p style="padding-left: 20px;">(a) the step of receiving a carrier transmission;</p> <p style="padding-left: 20px;">(b) the step of demodulating said carrier transmission to detect an information transmission</p>

<p><u>one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information, based on said step of organizing;</u> generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>
---	---

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 14
<p>152. A method of <u>delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein</p>	<p>14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

<p><u>said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 14
<p>157. A method of <u>delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>14. A method of processing signals including:</p> <p>(a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 14
<p>162. A method of <u>delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 14
<p>167. A method of <u>outputting a video graphic presentation</u> at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed</u></p>	<p>14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to</p>

<p><u>first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>said devices of said embedded signals.</p>
---	---

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 14
<p>171. A method of <u>delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image,</u> wherein said first completed full-screen video graphic</p>	<p>14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon; (c) the step of detecting and identifying embedded signals on said information transmission; (d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals; (e) the step of controlling said devices based on the instructions within said embedded signals; and (f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>

<p><u>image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;"><u>wherein said method delivers said video graphic presentation.</u></p>	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 14
<p>175. A method of <u>delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving, at an origination transmitter station, a first</u></p>	<p>14. A method of processing signals including:</p> <p style="padding-left: 20px;">(a) the step of receiving a carrier transmission;</p> <p style="padding-left: 20px;">(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p style="padding-left: 20px;">(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p style="padding-left: 20px;">(d) the step of passing said embedded signals to a device or devices to be controlled based on</p>

<p><u>completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>instructions identified within said embedded signals;</p> <p>(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p>(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 14
177. A method of <u>delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor	14. A method of processing signals including: (a) the step of receiving a carrier transmission; (b) the step of demodulating said carrier transmission to detect an information transmission thereon;

<p>that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>(c) the step of detecting and identifying embedded signals on said information transmission;</p> <p>(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;</p> <p>(e) the step of controlling said devices based on the instructions within said embedded signals; and</p> <p>(f) the step of recording the receipt of and passing to said devices of said embedded signals.</p>
--	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 14
<p>179. A method of <u>outputting a video graphic presentation</u> at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u></p> <p><u>passing said received series of video images to a</u></p>	<p>14. A method of processing signals including:</p> <p>(a) the step of receiving a carrier transmission;</p> <p>(b) the step of demodulating said carrier transmission to detect an information transmission thereon;</p> <p>(c) the step of detecting and identifying embedded signals on said information transmission;</p>

video monitor for delivery to a user, said video monitor having a viewing screen;
displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;
detecting said at least a first discrete signal;
passing said at least a first discrete signal to at least one processor;
organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;
responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;
passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and
displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,
wherein said method delivers said video graphic presentation.

(d) the step of passing said embedded signals to a device or devices to be controlled based on instructions identified within said embedded signals;
(e) the step of controlling said devices based on the instructions within said embedded signals; and
(f) the step of recording the receipt of and passing to said devices of said embedded signals.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 20
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 20
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u> said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, <u>wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to</p>

<p>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 20
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 20
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 20
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with</u> 	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated

<p><u>information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>with said selected stations, and causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	--

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 20
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation,</u> said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data; transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction;</u> and transferring said at least one control signal to said at least one transmitter, and transmitting at least one</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

information transmission containing said at least said first discrete signal and said at least one control signal.	
--	--

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 20
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 20px;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 20px;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p style="padding-left: 20px;">transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p style="padding-left: 20px;">detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p style="padding-left: 20px;">causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 20
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing</p>

one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:

receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;

transferring said at least one instruct signal to at least one transmitter;

receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and

transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.

data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:

transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,

detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and

causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 20
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to</p>

<p>transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>accommodate a special user application, comprising the steps of: transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 20
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information, based on said step of organizing;</u> generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of: transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 20
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals. 	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 20
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output</p>

<p>adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 20
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated</p>

discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.
--	---

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 20
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 20
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.	
--	--

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 20
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.	
--	--

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 20
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist,</p> <p>detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 20
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image, wherein said method delivers said video graphic presentation. 	<p>20. A method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, comprising the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, detecting the presence of said instruct-to-generate signal at selected receiver stations and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computer to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 24
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 24
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

<p>instructions to a transmitter;</p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
--	--

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 24
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 24
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal,</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with</p>

<p>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, <u>wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.
---	--

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 24
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing 	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <ul style="list-style-type: none"> transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

<p>said at least one processor instruction; generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</p>	
--	--

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 24
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 24
116. A method of delivering a video presentation	24. In a method of generating computer output at a

<p>at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 24
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p>receiving at at least one of said first remote transmitter station and a second remote transmitter</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their</p>

<p>station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 24
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to</p>

<p>within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing</u>;</p> <p> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p> generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</p> <p> outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</p>	<p>each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 24
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p> passing said received video image to an output device for delivery to a user;</p> <p> detecting said at least one first discrete signal;</p> <p> passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal</u>;</p> <p> responding, at said processor, to <u>processor instructions comprising said organized information, based on said step of organizing</u>;</p> <p> generating a signal based on said processor instructions; and</p> <p> outputting at least a portion of said video presentation based on said generated signal.</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p> transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p> causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 24
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify</p>

<p>station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 24
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 24
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 24
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to</p>

<p>screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 24
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said</p>

<p>said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 24
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify</p>

<p>method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	--

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 24
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and</p>

<p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 24
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p>	<p>24. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers, being programmed to accommodate a special user application, the steps of:</p> <p>transmitting an instruct-to-generate signal to said computers at a time when corresponding user specific output information content does not exist, and</p> <p>causing said last named computers to generate their</p>

passing said at least a first discrete signal to at least one processor;
organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;
responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;
passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and
displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,
wherein said method delivers said video graphic presentation.

user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Application Claim 56	U.S. Pat. No. 4,965,825, Claim 25
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</p> <p>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 75	U.S. Pat. No. 4,965,825, Claim 25
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, <u>wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image,</u> said downloadable processor instructions having at said at least one</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated</p>

<p>receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 4,965,825, Claim 25
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 4,965,825, Claim 25
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, <u>wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals</u>, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video; transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <ul style="list-style-type: none"> detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 4,965,825, Claim 25
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at 	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to</p>

<p>said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</p> <p>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</p>	<p>process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
---	---

Application Claim 110	U.S. Pat. No. 4,965,825, Claim 25
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p>receiving at at least one transmitter station at least a first discrete signal containing information, <u>wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal,</u> said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to</p>

<p>processor to process data; transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, <u>wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction;</u> and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 4,965,825, Claim 25
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</p> <p>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, <u>wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time;</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

<p>and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 4,965,825, Claim 25
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 20px;">receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, <u>said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of</u></p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p style="padding-left: 20px;">detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p style="padding-left: 20px;">causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

<p><u>receiver stations; and</u> transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 142	U.S. Pat. No. 4,965,825, Claim 25
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; generating only a portion of said video image based on said step of responding to said at least one processor instruction; and outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of: detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 143	U.S. Pat. No. 4,965,825, Claim 25
143. A method of outputting a video presentation	25. In a method of generating computer output at a

<p>at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information, based on said step of organizing;</u> generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <ul style="list-style-type: none"> detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.
---	---

Application Claim 152	U.S. Pat. No. 4,965,825, Claim 25
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or</u> 	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <ul style="list-style-type: none"> detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said

<p><u>more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>output devices being different, with each output signal specific to a specific user.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 4,965,825, Claim 25
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 4,965,825, Claim 25
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code,</u> and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image; transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <ul style="list-style-type: none"> detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 4,965,825, Claim 25
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full- 	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Application Claim 171	U.S. Pat. No. 4,965,825, Claim 25
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p>

<p>video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>
--	---

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 175	U.S. Pat. No. 4,965,825, Claim 25
175. A method of delivering a video graphic	25. In a method of generating computer output at a

presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:

receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;

delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;

receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and

transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,

wherein said method delivers said video graphic presentation.

multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:

detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and

causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 4,965,825, Claim 25
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 179	U.S. Pat. No. 4,965,825, Claim 25
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</p> <p>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>25. In a method of generating computer output at a multiplicity of receiver stations each of which includes a computer adapted to generate and transmit user specific output information content and user specific signals to one or more associated output devices, with at least some of said computers being programmed to process modification control signals so as to modify said computers' method of processing data and generating output information content, each of said computers being programmed to accommodate a special user application, the steps of:</p> <p>detecting at selected receiver stations the presence of an instruct-to-generate signal transmitted by a transmission source and coupling said instruct-to-generate signal to the computers associated with said selected stations, and</p> <p>causing said last named computers to generate their user specific output information content in response to said instruct-to-generate signal, thereby to transmit to each of their associated output devices an output signal comprising the user specific output information content and the user specific signal of its associated computer, the output signals at a multiplicity of said output devices being different, with each output signal specific to a specific user.</p>

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 1
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output directing function of said switch means.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 1
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output directing function of said switch means.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 1
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 1
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p style="padding-left: 20px;">a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 1
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>programming received from one or more said receiver/distribution means to an associated output device, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 1
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 1
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 1
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output directing function of said switch means.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 1
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output directing function of said switch means.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 1
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <ul style="list-style-type: none"> a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 1
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <ul style="list-style-type: none"> a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>a second processor means for controlling the output directing function of said switch means.</p>
--	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 1
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 1
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;"><u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p style="padding-left: 40px;">a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 1
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p style="padding-left: 40px;"><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 1
171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,

a plurality of detector means for detecting control signals respecting said programming,

a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,

a storage means for receiving and storing said detected control signals, and

a second processor means for controlling the output directing function of said switch means.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 1
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output directing function of said switch means.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 1
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output directing function of said switch means.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 1
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>1. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of directing a selected portion of said programming received from one or more said receiver/distribution means to an associated output device, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a storage means for receiving and storing said detected control signals, and a second processor means for controlling the output directing function of said switch means.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 2
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>2. In a signal processing system,</p> <p>a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means,</p> <p>a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a buffer/memory storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output function of said switch means.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 2
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>2. In a signal processing system,</p> <p>a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means,</p> <p>a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a buffer/memory storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output function of said switch means.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 2
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 2
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 2
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 2
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 2
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 2
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 2
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>2. In a signal processing system,</p> <p>a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means,</p> <p>a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a buffer/memory storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output function of said switch means.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 2
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 2
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>a second processor means for controlling the output function of said switch means.</p>
--	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 2
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 2
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>2. In a signal processing system,</p> <p>a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means,</p> <p>a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a buffer/memory storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output function of said switch means.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 2
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>2. In a signal processing system,</p> <p>a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means,</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u></p> <p><u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u></p> <p><u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u></p> <p><u>detecting said at least a first discrete signal of said downloadable code;</u></p> <p><u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p><u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a buffer/memory storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output function of said switch means.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 2
171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,

a plurality of detector means for detecting control signals respecting said programming,

a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,

a buffer/memory storage means for receiving and storing said detected control signals, and

a second processor means for controlling the output function of said switch means.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 2
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>2. In a signal processing system,</p> <p>a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means,</p> <p>a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a buffer/memory storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output function of said switch means.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 2
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>2. In a signal processing system,</p> <p>a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means,</p> <p>a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing,</p> <p>a plurality of detector means for detecting control signals respecting said programming,</p> <p>a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means,</p> <p>a buffer/memory storage means for receiving and storing said detected control signals, and</p> <p>a second processor means for controlling the output function of said switch means.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 2
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>2. In a signal processing system, a plurality of receiver/distribution means for receiving programming from a program source and for inputting said programming to a switch means and a plurality of detector means, a switch means for receiving output from said plurality of receiver/distribution means, said switch means being capable of outputting a selected portion of said programming received from one or more said receiver/distribution means to a device for further processing, a plurality of detector means for detecting control signals respecting said programming, a first processor means operatively connected to said plurality of detector means for identifying each detected control signal as having been detected by a particular detector means, a buffer/memory storage means for receiving and storing said detected control signals, and a second processor means for controlling the output function of said switch means.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 3
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 3
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u></p> <p>said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>having been detected by a particular detector means,</p> <p>a storage/ transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 3
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	function of said matrix switch and the transfer function of said storage/transfer means.
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 3
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>3. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 3
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</u></p>	<p>3. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 3
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 3
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said</p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	function of said storage/transfer means.
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 3
<p>123. <u>A method of delivering a video presentation at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>3. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 3
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>3. In a signal processing system,</p> <p style="padding-left: 20px;">a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p style="padding-left: 20px;">a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 20px;">a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p style="padding-left: 20px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 3
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>3. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 3
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>3. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices, a plurality of detector means for detecting control signals respecting said programming, each detector</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 3
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 3
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u></p> <p><u>delivering said video image to a transmitter;</u></p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 3
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>3. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 3
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 2em;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 2em;"><u>transferring said at least one discrete signal to a transmitter;</u></p> <p style="padding-left: 2em;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 2em;"><u>transferring said one or more control signals to said transmitter; and</u></p> <p style="padding-left: 2em;"><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>3. In a signal processing system,</p> <p style="padding-left: 2em;">a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p style="padding-left: 2em;">a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p style="padding-left: 2em;">a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 2em;">a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p style="padding-left: 2em;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 2em;">a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

<u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 3
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;"><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p style="padding-left: 20px;"><u>transmitting a transmission that contains said at</u></p>	<p>3. In a signal processing system,</p> <p style="padding-left: 20px;">a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p style="padding-left: 20px;">a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 20px;">a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p style="padding-left: 20px;">a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

<u>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 3
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</u></p>	<p>3. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

<u>receiver station,</u> <u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 3
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>3. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for transmitting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for directing selected portions of said received programming to one or more output devices, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the directing function of said matrix switch and the transfer function of said storage/transfer means.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 4
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 4
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>control signals identifying each control signal as having been detected by a particular detector means, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 4
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>4. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	function of said matrix switch and the transfer function of said buffer means.
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 4
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>4. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 4
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</u></p>	<p>4. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 4
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 4
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said</p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	function of said buffer means.
--	--------------------------------

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 4
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 4
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 4
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>4. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 4
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>4. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording, a plurality of detector means for detecting control</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 4
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 4
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 4
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>4. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 4
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 2em;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 2em;"><u>transferring said at least one discrete signal to a transmitter;</u></p> <p style="padding-left: 2em;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 2em;"><u>transferring said one or more control signals to said transmitter; and</u></p> <p style="padding-left: 2em;"><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>4. In a signal processing system,</p> <p style="padding-left: 2em;">a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p style="padding-left: 2em;">a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p style="padding-left: 2em;">a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 2em;">a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p style="padding-left: 2em;">a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 2em;">a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

<p><u>wherein said method delivers said video graphic presentation.</u></p>	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 4
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;"><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p style="padding-left: 20px;"><u>transmitting a transmission that contains said at</u></p>	<p>4. In a signal processing system,</p> <p style="padding-left: 20px;">a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p style="padding-left: 20px;">a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p style="padding-left: 20px;">a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p style="padding-left: 20px;">a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p style="padding-left: 20px;">a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p style="padding-left: 20px;">a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

<u>least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 4
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one</u></p>	<p>4. In a signal processing system,</p> <p>a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means,</p> <p>a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording,</p> <p>a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means,</p> <p>a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

<u>receiver station,</u> <u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 4
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>4. In a signal processing system, a receiver/distributor means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means, a matrix switch means for receiving said programming from such a receiver/distributor means and for outputting selected portions of said received programming to one or more output devices for further processing or recording, a plurality of detector means for detecting control signals respecting said programming, each detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a processor means operatively connected to said plurality of detector means for adding data to said control signals identifying each control signal as having been detected by a particular detector means, a buffer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output function of said matrix switch and the transfer function of said buffer means.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 5
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>5. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 5
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable</u></p>	<p>5. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing</p>

<p><u>processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 5
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from</p>	<p>5. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

said origination transmitter before a specific time.	
--	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 5
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 5
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p>

<p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 5
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to</p>

<p><u>processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 5
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the</p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

<p>communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 5
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

<p>identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 5
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>5. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 5
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 5
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring</p>

<p><u>said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 5
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>5. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p>

or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.	a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.
--	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 5
162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u> , said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 5
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 5
171. <u>A method of delivering a video graphic</u>	5. In a signal processing system,

presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,

a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and

a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 5
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more</u></p>	<p>5. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

<u>control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,109,414, Claim 5
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic</u></p>	<p>5. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

presentation.

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,109,414, Claim 5
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>5. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a recording device operatively connected to a broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,109,414, Claim 6
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,109,414, Claim 6
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within</p>

<p><u>processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,109,414, Claim 6
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output</p>

transmitting said at least one control signal from said origination transmitter before a specific time.	functions of said matrix switch means and the transfer functions of said storage/transfer means.
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,109,414, Claim 6
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,109,414, Claim 6
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix</p>

<p>method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,109,414, Claim 6
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information</u></p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring</p>

<p><u>contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,109,414, Claim 6
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said</p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer</p>

remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	functions of said storage/transfer means.
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,109,414, Claim 6
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of</u></p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

<p><u>receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,109,414, Claim 6
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,109,414, Claim 6
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,109,414, Claim 6
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p>

<p><u>presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,109,414, Claim 6
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined</p>

<p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,109,414, Claim 6
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,109,414, Claim 6
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>6. In a signal processing system, a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means, a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means, a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detected said control signals in a predetermined frequency range or at a predetermined location within said programming, a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,109,414, Claim 6
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</u></p>	<p>6. In a signal processing system,</p> <p>a receiver/distribution means for receiving programming from a plurality of program sources and for outputting said programming to a matrix switch means and a control signal detector means,</p> <p>a matrix switch means for receiving said programming from said receiver/distributor means and for outputting selected portions of said received programming to a broadcast transmission means and/or a recording device operatively connected to said broadcast transmission means,</p> <p>a control signal detector means for detecting control signals respecting said programming and transferring said control signals to a storage/transfer means, said control signal detector means being configured to detect said control signals in a predetermined frequency range or at a predetermined location within said programming,</p> <p>a storage/transfer means for receiving and storing said control signals and for transferring at least a portion of said control signals for further processing, and</p> <p>a processor means for controlling the output functions of said matrix switch means and the transfer functions of said storage/transfer means.</p>

<u>wherein said method delivers said video graphic presentation.</u>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,109,414, Claim 6
